A non-perturbative lattice regularization of chiral fermions and bosons with anomaly-free symmetry G in 1+1D spacetime is proposed. More precisely, we ask "whether there is a local short-range quantum Hamiltonian with a finite Hilbert space for a finite system realizing onsite symmetry G defined on a 1D spatial lattice with continuous time, such that its low energy physics produces a 1+1D anomaly-free chiral matter theory of symmetry G?" In particular, we show that the 3_L - 5_R - 4_L - 0_R U(1) chiral fermion theory, with two left-moving fermions of charge-3 and 4, and two right-moving fermions of charge-5 and 0 at low energy, can be put on a 1D spatial lattice where the U(1) symmetry is realized as an onsite symmetry, if we include properly designed multi-fermion interactions with intermediate strength. In general, we propose that any 1+1D U(1)-anomaly-free chiral matter theory can be defined as a finite system on a 1D lattice with onsite symmetry by using a quantum Hamiltonian with continuous time, but without suffered from Nielsen-Ninomiya theorem's fermion-doubling, if we include properly-designed interactions between matter fields. We propose how to design such interactions by looking for extra symmetries via bosonization/fermionization. We comment on the new ingredients and the differences of ours compared to Ginsparg-Wilson fermion, Eichten-Preskill and Chen-Giedt-Poppitz (CGP) models, and suggest modifying CGP model to have successful mirror-decoupling. As an additional remark, we show a topological non-perturbative proof on the equivalence relation between the 't Hooft anomaly matching conditions and the boundary fully gapping rules (e.g. Haldane's stability conditions for Luttinger liquid) of U(1) symmetry. Our proof holds universally independent from Hamiltonian or Lagrangian/path integral formulation of quantum theory.

I. INTRODUCTION AND SUMMARY

Regulating and defining chiral fermion field theory is a very important problem, since the standard model is one such theory. 1-5 However, the fermion-doubling problem⁶⁻¹⁰ makes it very difficult to define chiral fermions (in an even dimensional spacetime) on the lat-There is much previous research that tries to solve this famous problem. One approach is the lattice gauge theory, 11 which is unsuccessful since it cannot reproduce chiral couplings between the gauge fields and the fermions. Another approach is the domain-wall fermion. 12,13 However, the gauge field in the domain-wall fermion approach propagates in one-higher dimension. Another approach is the overlap-fermion, 9,14–16 while the path-integral in the overlap-fermion approach may not describe a finite quantum theory with a finite Hilbert space for a finite space-lattice. There is also the mirror fermion approach^{17–20} which starts with a lattice model containing chiral fermions in one original light sector coupled to gauge theory, and its chiral conjugated as the mirror sector. Then, one tries to include direct interactions or boson mediated interactions^{21,22} between fermions to gap out the mirror sector only. However, the later works either fail to demonstrate^{23–25} or argue that it is almost impossible to gap out (i.e. fully open the energy gaps of) the mirror sector without breaking the gauge symmetry in some mirror fermion models.²⁶

We realized that the previous failed lattice-gauge approaches always assume non-interacting lattice fermions (apart from the interaction to the lattice gauge field). In this work, we show that lattice approach actually works if we include direct fermion-fermion interaction with appropriate strength (i.e. the dimensionaless coupling constants are of order 1).^{27,28} In other words, a general framework of the mirror fermion approach actually works for constructing a lattice chiral fermion theory, at least in 1+1D. Specifically, any anomaly-free chiral fermion/boson field theory can be defined as a finite quantum system on a 1D lattice where the (gauge or global) symmetry is realized as an onsite symmetry, provided that we allow lattice fermion/boson to have interactions, instead of being free. (Here, the "chiral" theory here means that it "breaks parity P symmetry." Our 1+1D chiral fermion theory breaks parity P and time reversal T symmetry. See Appendix A for C, P, T symmetry in 1+1D.) Our insight comes from Ref. 27,28, where the connection between gauge anomalies and symmetryprotected topological (SPT) states²⁹ (in one-higher dimension) is found.

To make our readers fully appreciate our thinking, we shall firstly define our important basic notions clearly: (\$\(\int \) Onsite symmetry^{29,30} means that the overall symmetry transformation U(g) of symmetry group G can be defined as the tensor product of each single site's symmetry transformation $U_i(g)$, via $U(g) = \otimes_i U_i(g)$ with $g \in G$. Nonsite symmetry: means $U(g)_{\text{non-onsite}} \neq \otimes_i U_i(g)$. (\$\(\int \) Local Hamiltonian with short-range interactions means that the non-zero amplitude of matter(fermion/boson) hopping/interactions in finite time has a finite range propagation, and cannot be an infinite range. Strictly speaking, the quasi-local exponential decay (of kinetic hopping/interactions) is non-local and not short-ranged.

 $(\diamond 3)$ finite(-Hilbert-space) system means that the dimension of Hilbert space is finite if the system has finite lattice sites (e.g. on a cylinder).

Nielsen-Ninomiya theorem $^{6-8}$ states that the attempt to regularize chiral fermion on a lattice as a local *free non-interacting* fermion model with fermion number conservation (*i.e.* with U(1) symmetry³¹) has fermion-doubling problem $^{6-10}$ in an even dimensional spacetime. To apply this no-go theorem, however, the symmetry is assumed to be an onsite symmetry.

Ginsparg-Wilson fermion approach copes with this no-go theorem by solving Ginsparg-Wilson(GW) relation^{32,33} based on the quasi-local Neuberger-Dirac operator,^{34–36} where quasi-local is strictly non-local. In this work, we show that the quasi-localness of Neuberger-Dirac operator in the GW fermion approach imposing a non-onsite^{29,37,38} U(1) symmetry, instead of an onsite symmetry. (While here we simply summarize the result, one can read the details of onsite and non-onsite symmetry, and its relation to GW fermion in the Appendix B.) For our specific approach for the mirror-fermion decoupling, we will not implement the GW fermions

(of non-onsite symmetry) construction, instead, we will use a lattice fermions with onsite symmetry but with particular properly-designed interactions. Comparing GW fermion to our approach, we see that

- Ginsparg-Wilson(GW) fermion approach obtains "chiral fermions from a local free fermion lattice model with non-onsite U(1) symmetry (without fermion doublers)." (Here one regards Ginsparg-Wilson fermion applying the Neuberger-Dirac operator, which is strictly non-onsite and non-local.)
- Our approach obtains "chiral fermions from local interacting fermion lattice model with onsite U(1) symmetry (without fermion doublers), if all U(1) anomalies are cannelled."

Also, the conventional GW fermion approach discretizes the Lagrangian/the action on the spacetime lattice, while we use a local short-range quantum Hamiltonian on 1D spatial lattice with a continuous time. Such a distinction causes some difference. For example, it is known that Ginsparg-Wilson fermion can implement a single Weyl fermion for the free case without gauge field on a 1+1D space-time-lattice due to the works of Neuberger, Lüscher, etc. Our approach cannot implement a single Weyl fermion on a 1D space-lattice within local short-range Hamiltonian. (However, such a distinction may not be important if we are allowed to introduce a non-local infinite-range hopping.)

Comparison to Eichten-Preskill and Chen-Giedt-Poppitz models: Due to the past investigations, a majority of the high-energy lattice community believes that the mirror-fermion decoupling (or lattice gauge approach) fails to realize chiral fermion or chiral gauge theory. Thus one may challenge us by asking "how our mirror-fermion decoupling model is different from Eichten-Preskill and Chen-Giedt-Poppitz models?" And "why the recent numerical attempt of Chen-Giedt-Poppitz fails?²⁵" We now stress that, our approach provides properly designed fermion interaction terms to make things work, due to the recent understanding to topological gapped boundary conditions^{39–42}:

• Eichten-Preskill (EP)¹⁷ propose a generic idea of the mirror-fermion approach for the chiral gauge theory. There the perturbative analysis on the weak-coupling and strong-coupling expansions are used to demonstrate possible mirror-fermion decoupling phase can exist in the phase diagram. The action is discretized on the spacetime lattice. In EP approach, one tries to gap out the mirror-fermions via the mass term of composite fermions that do not break the (gauge) symmetry on lattice. The mass term of composite fermions are actually fermion interacting terms. So in EP approach, one tries to gap out the mirror-fermions via the direct fermion interaction that do not break the (gauge) symmetry

on lattice. However, considering only the symmetry of the interaction is not enough. Even when the mirror sector is anomalous, one can still add the direct fermion interaction that do not break the (gauge) symmetry. So the presence of symmetric direct fermion interaction may or may not be able to gap out the mirror sector. When the mirror sector is anomaly-free, we will show in this paper, some symmetric interactions are helpful for gapping out the mirror sectors, while other symmetric interactions are harmful. The key issue is to design the proper interaction to gap out the mirror section, and considering only symmetry is not enough.

- Chen-Giedt-Poppitz (CGP)²⁵ follows the EP general framework to deal with a 3-4-5 anomaly-free model with a single U(1) symmetry. All the U(1) symmetry-allowed Yukawa-Higgs terms are introduced to mediate multi-fermion interactions. The Ginsparg-Wilson fermion and the Neuberger's overlap Dirac operator are implemented, the fermion actions are discretized on the spacetime lattice. Again, the interaction terms are designed only based on symmetry, which contain both helpful and harmful terms, as we will show.
- Our model in general belongs to the mirrorfermion-decoupling idea. The anomaly-free model we proposed is named as the 3_L - 5_R - 4_L - 0_R model. Our 3_L - 5_R - 4_L - 0_R is in-reality different from Chen-Giedt-Poppitz's 3-4-5 model, since we impliment: (i) an onsite-symmetry local lattice model: Our lattice Hamiltonian is built on 1D spatial lattice with on-site U(1) symmetry. We neither implement the GW fermion nor the Neuberger-Dirac operator (both have non-onsite symmetry). (ii) a particular set of interaction terms with proper strength: Our multi-fermion interaction terms are particularly-designed gapping terms which obey not only the symmetry but also certain Lagrangian subgroup algebra. Those interaction terms are called *helpful* gapping terms, satisfying Boundary Fully Gapping Rules. We will show that the Chen-Giedt-Poppitz's Yukawa-Higgs terms induce extra multi-fermion interaction terms which do not satsify **Boundary** Fully Gapping Rules. Those extra terms are incompatible harmful terms, competing with the helpful gapping terms and causing the preformed energy gap (which is not a usual quadratic mass gap) unstable so preventing the mirror sector from being gapped out. (This can be one of the reasons for the failure of mirror-decoupling in Ref.25.) We stress that, due to a topological non-perturbative reason, only a particular set of ideal interaction terms are helpful to fully gap the mirror sector. Adding more or removing interactions can cause the energy gap unstable thus the phase flowing to gapless states. In addition, we stress that only

when the helpful interaction terms are in a proper range, intermediate strength for dimensionless coupling of order 1, can they fully gap the mirror sector, and yet not gap the original sector (details in Sec.IIIB). Throughout our work, when we say strong coupling for our model, we really mean intermediate(-strong) coupling in an appropriate range. In CGP model, however, their strong coupling may be too strong (with their kinetic term neglected); which can be another reason for the failure of mirror-decoupling.²⁵

(iii) extra symmetries: For our model, a total even number N of left/right moving Weyl fermions $(N_L = N_R = N/2)$, we will add only N/2 helpful gapping terms under the constraint of the Lagrangian subgroup algebra and Boundary Fully Gapping Rules. As a result, the full symmetry of our lattice model is $U(1)^{N/2}$ (where the gapping terms break $U(1)^N$ down to $U(1)^{N/2}$). For the case of our 3_L - 5_R - 4_L - 0_R model, the full U(1)² symmetry has two sets of U(1) charges, $U(1)_{1st}$ 3-5-4-0 and $U(1)_{2nd}$ 0-4-5-3, both are anomaly-free and mixed-anomaly-free. Although the physical consideration only requires the interaction terms to have on-site $U(1)_{1st}$ symmetry, looking for interaction terms with extra U(1) symmetry can help us to identify the helpful gapping terms and design the proper lattice interactions. CGP model has only a single $U(1)_{1st}$ symmetry. Here we suggest to improve that model by removing all the interaction terms that break the $U(1)_{2nd}$ symmetry (thus adding all possible terms that preserve the two U(1)symmetries) with an intermediate strength.

The plan and a short summary (see Fig. 1) of our paper are the following. In Sec.II we first consider a 3_L - 5_R - 4_L - 0_R anomaly-free chiral fermion field theory model, with a full U(1)² symmetry: A first 3-5-4-0 U(1)_{1st} symmetry for two left-moving fermions of charge-3 and charge-4, and for two right-moving fermions of charge-5 and charge-0. And a second 0-4-5-3 U(1)_{2nd} symmetry for two left-moving fermions of charge-0 and charge-5, and for two right-moving fermions of charge-4 and charge-3. If we wish to have a *single* U(1)_{1st} symmetry, we can weakly break the U(1)_{2nd} symmetry by adding tiny local U(1)_{2nd}-symmetry breaking term.

We claim that this model can be put on the lattice with an onsite U(1) symmetry, but without fermion-doubling problem. We construct a 2+1D lattice model by simply using four layers of the zeroth Landau levels(or more precisely, four filled bands with Chern numbers 43 -1, +1, -1, +1 on a lattice 44,45) which produces charge-3 left-moving, charge-5 right-moving, charge-4 left-moving, charge-0 right-moving, totally four fermionic modes at low energy on one edge. Therefore, by putting the 2D bulk spatial lattice on a cylinder with two edges, one can leave edge states on one edge untouched so they remain chiral and gapless, while turning on interactions to gap

out the mirrored edge states on the other edge with a large energy gap (which is not a usual quadratic mass gap).

In Sec.III, we provide a correspondence from the continuum field theory to a discrete lattice model. The numerical result of the chiral- π flux square lattice with nonzero Chern numbers, supports the free fermion part of our model. We study the kinetic and interacting part of Hamiltonian with dimensional scaling, energy scale and interaction strength analysis. In Sec.IV, we justify the mirrored edge can be gapped by analytically bosonizing the fermion theory and confirm the interaction terms obeys "the boundary fully gapping rules."

To consider a more general model construction, inspired by the insight of SPT, ^{27–29} in Sec.IV A, we apply the bulk-edge correspondence between Chern-Simons theory and the chiral boson theory. $^{39,41,42,48,50,53-56}$ We refine and make connections between the key concepts in our paper in Sec.IVB, IVC. These are "the anomaly factor^{5,57–59}" and "effective Hall conductance" " 't Hooft anomaly matching condition^{58,59}" and "the boundary fully gapping rules. 39-42,48,50,52" In Sec.V, a non-perturbative lattice definition of 1+1D anomaly-free chiral matter model is given, and many examples of fermion/boson models are provided. These model constructions are supported by our proof of the equivalence relations between "the anomaly matching condition" and "the boundary fully gapping rules" in the Appendix C and D.

In Fig. 1, we put these various models with various effective energy scales into a renormalization group (RG) perspective from the UV (ultraviolet: high energy and short distance) to IR (infrared: low energy and long distance):

- UV lattice Hamiltonian fermion model,
- UV continuum (fermion/boson) field theory, and
- IR fixed-point chiral fermion theory.

In contrast, we do not directly implement in our work:

• UV lattice field theory regularization,

which is the conventional method for the lattice QCD community. In other words, we do not attempt to directly discretize "the UV fermion field theory" (to be shown in Eq. (3) and (65)) on a lattice in order to obtain the "UV lattice field theory model." Namely, we do not attempt to perform the analysis shown along the dotted arrows (\cdots) in Fig. 1.

However, we analyze or comment on all the other RG flows and the other correspondences (bosonization/fermionization in 1+1D) shown in Fig. 1. We formulate a UV lattice Hamiltonian model instead (to be shown in Eq. (7) and (66)) at a higher energy scale $\Lambda_{3,\rm UV}$ ($\simeq 1/a$), whose emergent effective UV field theory at a lower energy scale $\Lambda_{1,\rm UV}$ becomes the UV continuum fermionic field theory (to be shown in Eq. (3) and (65)) or the UV continuum bosonic field theory (to be shown in Eq. (4) and (64)). In addition, the emergent IR field theory at the deep IR becomes the desired "IR

fixed point chiral fermion field theory" (to be shown in Eq. (2)). In a short summary,

By providing a UV lattice Hamiltonian model (shown in Eq. (7) and (66)) whose emergent IR field theory at the deep IR becomes the desired "IR fixed point chiral fermion field theory" (shown in Eq. (2), we achieve our goal: a non-perturbative regularization of 1+1D anomaly-free chiral fermions and bosons on a lattice.

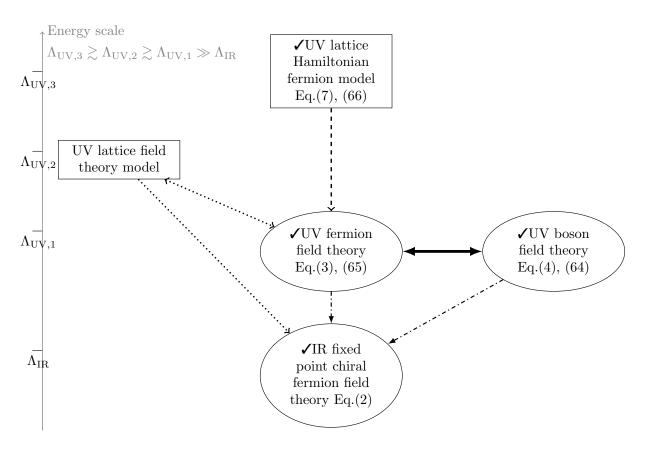

FIG. 1: We construct a UV (ultraviolet high-energy) lattice model in Eq. (7) and (66), whose energy scale $\Lambda_{3,\text{UV}} \simeq 1/a$. In contrast, the lattice QCD community usually employs a direct lattice regularization of a continuum field theory at another energy scale $\Lambda_{2,\text{UV}}$. In this work, we do *not* explore the UV lattice regularization of a field theory model. However, we consider the UV continuum field theory, including both the fermionic model (Eq. (3) and (65)) and the bosonic model (Eq. (4) and (64)) at another energy scale $\Lambda_{1,\text{UV}}$. The UV continuum field theory do *not* have to be renormalizable in the renormalization group (RG) sense; however, we provide a deeper UV completion of this UV continuum field theory by the UV Hamiltonian model at $\Lambda_{3,\text{UV}}$. In this work, we set the $\Lambda_{3,\text{UV}} \gtrsim \Lambda_{2,\text{UV}} \gtrsim \Lambda_{1,\text{UV}}$. Since the energy scale $\Lambda_{3,\text{UV}} \gtrsim \Lambda_{2,\text{UV}} \gtrsim \Lambda_{1,\text{UV}}$ is set about the same, the RG flow analysis can be controlled along the way. This includes the controlled RG flow ---. Here we do not study anything along the flows of two dotted arrows (···), since we do not attempt from the UV lattice field theory model (which is a conventional starting model of the lattice QCD community). We can also analyze along the two dashed-dotted arrows (-.-.-): We find that the RG flows to a completely gapped phase for the mirror sector, which is known in QFT and condensed matter literature. The boldface \longleftrightarrow arrow is based on the standard bosonization/fermionization method in 1+1D.

In Appendix A, we discuss the C, P, T symmetry in an 1+1 D fermion theory. In Appendix B, we show that GW fermions realizing its axial U(1) symmetry by a

non-onsite symmetry transformation. As the non-onsite symmetry signals the nontrivial edge states of bulk ${\rm SPT},^{29,37,38}$ thus GW fermions can be regarded as

gapless edge states of some bulk fermionic SPT states, such as certain topological insulators. We also explain why it is easy to gauge an onsite symmetry (such as our chiral fermion model), and why it is difficult to gauge a non-onsite symmetry (such as GW fermions). Since the lattice on-site symmetry can always be gauged, our result suggests a non-perturbative definition of any anomaly-free chiral gauge theory in 1+1D. In Appendix E, we provide physical, perturbative and non-perturbative understanding on "boundary fully gapping rules." In Appendix F, we provide more details and examples about our lattice models. With this overall understanding, in Sec.VI we summarize with deeper implications and future directions.

[Note on the terminology: Here in our work, U(1) symmetry may generically imply copies of U(1) symmetry such as $U(1)^M$, with positive integer M. (Topological) **Boundary Fully Gapping Rules** are defined as the rules to open the energy gap (which is not a usual quadratic mass gap) of the boundary states. (Topological) **Gapped Boundary Conditions** are defined to specify certain boundary types which are gapped (thus topological). There are two kinds of usages of *lattices* here discussed in our work: one is the **Hamiltonian lattice** model to simulate the chiral fermions/bosons. The other *lattice* is the **Chern-Simons lattice** structure of Hilbert space, which is a quantized lattice due to the level/charge quantization of Chern-Simons theory.]

Note added: After the completion of this present work in 2013, the authors have, later in 2018, reconstructed a variant version of the 1+1D lattice model in Ref. 60 realizing a 3_L - 5_R - 4_L - 0_R chiral fermion field theory. This is a variant lattice model but based on the same topological non-perturbative proof given in our Appendix A and B. Since our proof holds universally independent from Hamiltonian or Lagrangian/path integral formulation of quantum theory, the proof implies that the lattice regularization of 1+1D U(1) chiral fermion theory based on proper non-perturbative interactions must work successfully, regardless lattice Hamiltonian or lattice La-

grangian/path integral formulations.

In addition, recently in Ref. 61, we check the classifications of all 't Hooft anomalies (including nonperturbative global anomaly) for the weakly-gauged standard models from the 16n-number of chiral Weylfermions in 3+1D, the SO(10) grand unification (more precisely, Spin(10) chiral gauge theory). Ref. 61 shows that the only possible anomaly class is \mathbb{Z}_2 class for these weakly-gauged SO(10) for chiral Weyl-fermions in 3+1D. Which \mathbb{Z}_2 is generated by the new SU(2) anomaly found in Ref. 62. Ref. 61 also finds that the new SU(2) anomaly is absent in the SO(10) grand unification, therefore the SO(10) grand unification is all anomaly-free. A related analysis is performed in Ref. 63. Ref. 61 also finds that the same conclusion holds for the SO(18) grand unification (more precisely, the Spin(18) chiral gauge theory). This analysis supports the non-perturbatively lattice regularization of these "standard models" via a 3+1D local lattice model of Ref. 28,61

II. 3_L - 5_R - 4_L - 0_R CHIRAL FERMION MODEL

The simplest chiral (Weyl) fermion field theory with U(1) symmetry in 1 + 1D is given by the action

$$S_{\Psi,free} = \int dt dx \, \mathrm{i} \psi_L^{\dagger} (\partial_t - \partial_x) \psi_L. \tag{1}$$

However, Nielsen-Ninomiya theorem claims that such a theory cannot be put on a lattice with unbroken onsite U(1) symmetry, due to the fermion-doubling problem. $^{6-8}$ While the Ginsparg-Wilson fermion approach can still implement an anomalous single Weyl fermion on the lattice, our approach cannot (unless we modify local Hamiltonian to infinite-range hopping non-local Hamiltonian). As we will show, our approach is more restricted, only limited to the anomaly-free theory. Let us instead consider an anomaly-free 3_L - 5_R - 4_L - 0_R chiral fermion field theory with an action,

$$S_{\Psi_{A},free} = \int dt dx \left(i\psi_{L,3}^{\dagger} (\partial_{t} - \partial_{x}) \psi_{L,3} + i\psi_{R,5}^{\dagger} (\partial_{t} + \partial_{x}) \psi_{R,5} + i\psi_{L,4}^{\dagger} (\partial_{t} - \partial_{x}) \psi_{L,4} + i\psi_{R,0}^{\dagger} (\partial_{t} + \partial_{x}) \psi_{R,0} \right), \quad (2)$$

where $\psi_{L,3}$, $\psi_{R,5}$, $\psi_{L,4}$, and $\psi_{R,0}$ are 1-component Weyl spinor, carrying U(1) charges 3,5,4,0 respectively. The subscript L (or R) indicates left (or right) moving along $-\hat{x}$ (or $+\hat{x}$). Although this theory has equal numbers of left and right moving modes, it violates parity and time reversal symmetry, so it is a chiral theory (details about C, P, T symmetry in Appendix A). Such a chiral fermion field theory is very special because it is free

from U(1) anomaly - it satisfies the anomaly matching condition^{5,57–59} in 1+1D, which means $\sum_j q_{L,j}^2 - q_{R,j}^2 = 3^2 - 5^2 + 4^2 - 0^2 = 0$. We ask:

Question 1: "Whether there is a local finite Hamiltonian realizing the above U(1) 3-5-4-0 symmetry as an onsite symmetry with short-range interactions defined on a 1D spatial lattice with a continuous time, such that its low energy physics produces the anomaly-free chiral fermion theory Eq.(2)?"

Yes. We show that the above chiral fermion field theory can be put on a lattice with unbroken onsite U(1) symmetry, if we include properly-desgined interactions between fermions. In fact, we propose that the chiral fermion field theory in Eq.(2) appears as the low energy effective theory of the following 2+1D lattice model on a cylinder (see Fig.2) with a properly designed Hamiltonian. To derive such a Hamiltonian, we start from thinking the full two-edges fermion theory with the action S_{Ψ} , where the particularly chosen multi-fermion interactions $S_{\Psi_B,interact}$ will be explained:

$$S_{\Psi} = S_{\Psi_{A},free} + S_{\Psi_{B},free} + S_{\Psi_{B},interact} = \int dt \ dx \left(i\bar{\Psi}_{A}\Gamma^{\mu}\partial_{\mu}\Psi_{A} + i\bar{\Psi}_{B}\Gamma^{\mu}\partial_{\mu}\Psi_{B} \right)$$

$$+ \tilde{g}_{1}\left((\tilde{\psi}_{R,3})(\tilde{\psi}_{L,5})(\tilde{\psi}_{R,4}^{\dagger}\nabla_{x}\tilde{\psi}_{R,4}^{\dagger})(\tilde{\psi}_{L,0}\nabla_{x}\tilde{\psi}_{L,0}) + \text{h.c.} \right) + \tilde{g}_{2}\left((\tilde{\psi}_{R,3}\nabla_{x}\tilde{\psi}_{R,3})(\tilde{\psi}_{L,5}^{\dagger}\nabla_{x}\tilde{\psi}_{L,5}^{\dagger})(\tilde{\psi}_{R,4})(\tilde{\psi}_{L,0}) + \text{h.c.} \right),$$

$$(3)$$

The notation for fermion fields on the edge A are $\Psi_{\rm A}=(\psi_{L,3},\psi_{R,5},\psi_{L,4},\psi_{R,0})$, and fermion fields on the edge B are $\Psi_{\rm B}=(\tilde{\psi}_{L,5},\tilde{\psi}_{R,3},\tilde{\psi}_{L,0},\tilde{\psi}_{R,4})$. (Here a left moving mode in $\Psi_{\rm A}$ corresponds to a right moving mode in $\Psi_{\rm B}$ because of Landau level/Chern band chirality, the details of lattice model will be explained.) The gamma matrices in 1+1D are presented in terms of Pauli matrices, with $\gamma^0=\sigma_x,\,\gamma^1={\rm i}\sigma_y,\,\gamma^5\equiv\gamma^0\gamma^1=-\sigma_z,\,{\rm and}\,\,\Gamma^0=\gamma^0\oplus\gamma^0,\,\Gamma^1=\gamma^1\oplus\gamma^1,\,\Gamma^5\equiv\Gamma^0\Gamma^1$ and $\bar{\Psi}_i\equiv\Psi_i^\dagger\Gamma^0.$

In 1+1D, we can do bosonization, ⁶⁹ where the fermion matter field Ψ turns into bosonic phase field Φ , more explicitly $\psi_{L,3}\sim e^{\mathrm{i}\Phi_3^A}$, $\psi_{R,5}\sim e^{\mathrm{i}\Phi_5^A}$, $\psi_{L,4}\sim e^{\mathrm{i}\Phi_4^A}$, $\psi_{R,0}\sim e^{\mathrm{i}\Phi_3^A}$ on A edge, $\tilde{\psi}_{R,3}\sim e^{\mathrm{i}\Phi_3^B}$, $\tilde{\psi}_{L,5}\sim e^{\mathrm{i}\Phi_5^B}$, $\tilde{\psi}_{R,4}\sim e^{\mathrm{i}\Phi_4^A}$, $\tilde{\psi}_{L,0}\sim e^{\mathrm{i}\Phi_5^B}$ on B edge, up to normal orderings: $e^{\mathrm{i}\Phi}$: and prefactors, ⁷⁰ but the precise factor is not of our interest since our goal is to obtain its non-perturbative lattice realization. So Eq.(3) becomes

$$S_{\Phi} = S_{\Phi_{free}^{A}} + S_{\Phi_{free}^{B}} + S_{\Phi_{interact}^{B}} = \frac{1}{4\pi} \int dt dx \left(K_{IJ}^{A} \partial_{t} \Phi_{I}^{A} \partial_{x} \Phi_{J}^{A} - V_{IJ} \partial_{x} \Phi_{I}^{A} \partial_{x} \Phi_{J}^{A} \right) + \left(K_{IJ}^{B} \partial_{t} \Phi_{I}^{B} \partial_{x} \Phi_{J}^{B} - V_{IJ} \partial_{x} \Phi_{I}^{B} \partial_{x} \Phi_{J}^{B} \right) + \int dt dx \left(g_{1} \cos(\Phi_{3}^{B} + \Phi_{5}^{B} - 2\Phi_{4}^{B} + 2\Phi_{0}^{B}) + g_{2} \cos(2\Phi_{3}^{B} - 2\Phi_{5}^{B} + \Phi_{4}^{B} + \Phi_{0}^{B}) \right). \tag{4}$$

Here I,J runs over 3,5,4,0 and $K_{IJ}^{\rm A}=-K_{IJ}^{\rm B}={\rm diag}(1,-1,1,-1)$ $V_{IJ}={\rm diag}(1,1,1,1)$ are diagonal matrices.

All we have to prove is that gapping terms, the cosine terms with g_1, g_2 coupling can gap out all states on the edge B.

First, let us understand more about the full U(1) symmetry. What are the U(1) symmetries? They are transformations of

fermions
$$\psi \to \psi \cdot e^{iq\theta}$$
, bosons $\Phi \to \Phi + q \theta$

making the full action invariant. The original four Weyl fermions have a full $U(1)^4$ symmetry. Under two linear-independent interaction terms in $S_{\Psi_{\rm B},interact}$ (or $S_{\Phi_{interact}}^{\rm B}$), $U(1)^4$ is broken down to $U(1)^2$ symmetry. If

we denote these q as a charge vector $\mathbf{t} = (q_3, q_5, q_4, q_0)$, we find there are such two charge vectors

$$\mathbf{t}_1 = (3, 5, 4, 0) \text{ and } \mathbf{t}_2 = (0, 4, 5, 3)$$

for $U(1)_{1st}$, $U(1)_{2nd}$ symmetry respectively.

We emphasize that finding those gapping terms in this $\mathrm{U}(1)^2$ anomaly-free theory is not accidental. The **anomaly matching condition**^{5,57–59} here is satisfied, for the anomalies $\sum_j q_{L,j}^2 - q_{R,j}^2 = 3^2 - 5^2 + 4^2 - 0^2 = 0^2 - 4^2 + 5^2 - 3^2 = 0$, and the mixed anomaly: $3 \cdot 0 - 5 \cdot 4 + 4 \cdot 5 - 0 \cdot 3 = 0$ which can be formulated as

$$\boxed{\mathbf{t}_i^T \cdot (K^{\mathbf{A}}) \cdot \mathbf{t}_j = 0}, \quad i, j \in \{1, 2\}$$
 (5)

with the U(1) charge vector $\mathbf{t} = (3, 5, 4, 0)$, with its trans-

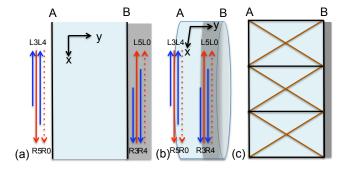

FIG. 2: 3-5-4-0 chiral fermion model: (a) The fermions carry U(1) charge 3,5,4,0 for $\psi_{L,3},\psi_{R,5},\psi_{L,4},\psi_{R,0}$ on the edge A, and also for its mirrored partners $\tilde{\psi}_{R,3},\tilde{\psi}_{L,5},\tilde{\psi}_{R,4},\tilde{\psi}_{L,0}$ on the edge B. We focus on the model with a periodic boundary condition along x, and a finite-size length along y, effectively as, (b) on a cylinder. (c) The ladder model on a cylinder with the t hopping term along black links, the t' hopping term along brown links. The shadow on the edge B indicates the gapping terms with G_1, G_2 couplings in Eq.(7) are imposed.

pose \mathbf{t}^T .

On the other hand, the **boundary fully gapping rules** (as we will explain, and the full details in Appendix E), 39,41,42,50 for a theory of Eq.(4), require two gapping terms, here $g_1 \cos(\ell_1 \cdot \Phi) + g_2 \cos(\ell_2 \cdot \Phi)$, such that self and mutual statistical angles $\theta_{ij}^{55,56}$ defined below among the Wilson-line operators ℓ_i, ℓ_j are zeros,

$$\theta_{ij}/(2\pi) \equiv \ell_i^T \cdot (K^{\mathrm{B}})^{-1} \cdot \ell_j = 0$$
, $i, j \in \{1, 2\}$ (6)

Indeed, here we have

$$\ell_1 = (1, 1, -2, 2), \quad \ell_2 = (2, -2, 1, 1)$$

satisfying the rules. We can alternatively choose:

$$\ell_1 = (3, -5, 4, 0), \quad \ell_2 = (0, 4, -5, 3).$$

Thus we prove that the mirrored edge states on the edge B can be fully gapped out.

We will prove the **anomaly matching condition** is equivalent to find a set of gapping terms $g_a \cos(\ell_a \cdot \Phi)$, satisfies the **boundary fully gapping rules**, detailed in Sec.IVB, IVC, Appendix C and D. Simply speaking,

The anomaly matching condition (Eq.(5)) in 1+1D is equivalent to (an if and only if relation) the boundary fully gapping rules (Eq.(6)) in 1+1D boundary/2+1D bulk for an equal number of left-right moving modes ($N_L = N_R$, with central charge $c_L = c_R$).

We prove this is true at least for U(1) symmetry case, with the bulk theory is a 2+1D SPT state and the boundary theory is in 1+1D.

We now propose a lattice Hamiltonian model for this 3_L - 5_R - 4_L - 0_R chiral fermion realizing Eq.(3) (thus Eq.(2) at the low energy once the Edge B is gapped out). Importantly, we do not discretize the action Eq.(3) on the spacetime lattice. We do not use Ginsparg-Wilson (GW) fermion nor the Neuberger-Dirac operator. GW and Neuberger-Dirac scheme contains non-onsite symmetry (details in Appendix B) which cause the lattice difficult to be gauged to chiral gauge theory. Instead, the key step is that we implement the on-site symmetry lattice fermion model. The free kinetic part is a fermion-hopping model which has a finite 2D bulk energy gap but with gapless 1D edge states. This can be done by using any lattice Chern insulator.

We stress that **any** lattice Chern insulator with onsite-symmetry shall work, and we design one as in Fig.2. (In fact, we later design another variant version of 1D lattice model in Ref. 60.) Our full Hamiltonian with two interacting G_1, G_2 gapping terms is

$$H = \sum_{q=3,5,4,0} \left(\sum_{\langle i,j \rangle} \left(t_{ij,q} \, \hat{f}_{q}^{\dagger}(i) \hat{f}_{q}(j) + h.c. \right) + \sum_{\langle \langle i,j \rangle \rangle} \left(t'_{ij,q} \, \hat{f}_{q}^{\dagger}(i) \hat{f}_{q}(j) + h.c. \right) \right)$$

$$+ G_{1} \sum_{j \in \mathcal{B}} \left(\left(\hat{f}_{3}(j) \right)^{1} \left(\hat{f}_{5}^{\dagger}(j) \right)^{1} \left(\hat{f}_{4}^{\dagger}(j)_{pt.s.} \right)^{2} \left(\hat{f}_{0}(j)_{pt.s.} \right)^{2} + h.c. \right) + G_{2} \sum_{j \in \mathcal{B}} \left(\left(\hat{f}_{3}(j)_{pt.s.} \right)^{2} \left(\hat{f}_{5}^{\dagger}(j)_{pt.s.} \right)^{2} \left(\hat{f}_{4}(j) \right)^{1} \left(\hat{f}_{0}(j) \right)^{1} + h.c. \right)$$

$$(7)$$

where $\sum_{j\in B}$ sums over the lattice points on the right boundary (the edge B in Fig.2), and the fermion operators \hat{f}_3 , \hat{f}_5 , \hat{f}_4 , \hat{f}_0 carry a U(1)_{1st} charge 3,5,4,0 and another U(1)_{2nd} charge 0,4,5,3 respectively. We emphasize that this lattice model has *onsite* U(1)² symmetry, since this Hamiltonian, including interaction terms, is invariant under a global U(1)_{1st} transformation on each site for any θ angle: $\hat{f}_3 \rightarrow \hat{f}_3 e^{\mathrm{i}3\theta}$, $\hat{f}_5 \rightarrow \hat{f}_5 e^{\mathrm{i}5\theta}$, $\hat{f}_4 \rightarrow \hat{f}_4 e^{\mathrm{i}4\theta}$, $\hat{f}_0 \rightarrow \hat{f}_0$, and invariant under another global U(1)_{2nd} transformation for any θ angle: $\hat{f}_3 \rightarrow \hat{f}_3$, $\hat{f}_5 \rightarrow \hat{f}_5 e^{\mathrm{i}4\theta}$, $\hat{f}_4 \rightarrow \hat{f}_4 e^{\mathrm{i}5\theta}$, $\hat{f}_0 \rightarrow \hat{f}_0 e^{\mathrm{i}3\theta}$. The U(1)_{1st} charge is the reason why it is named as 3_L - 5_R - 4_L - 0_R model.

As for notations, $\langle i,j \rangle$ stands for nearest-neighbor hopping along black links and $\langle \langle i,j \rangle \rangle$ stands for next-nearest-neighbor hopping along brown links in Fig.2. Here pt.s. stands for point-splitting. For example, $(\hat{f}_3(j)_{pt.s.})^2 \equiv \hat{f}_3(j)\hat{f}_3(j+\hat{x})$. We stress that the full Hamiltonian (including interactions) Eq.(7) is short-ranged and local, because each term only involves coupling within finite number of neighbor sites. The hopping amplitudes $t_{ij,3}=t_{ij,4}$ and $t'_{ij,3}=t'_{ij,4}$ produce bands with Chern number -1, while the hopping amplitudes $t_{ij,5}=t_{ij,0}$ and $t'_{ij,5}=t'_{ij,0}$ produce bands with Chern number +1 (see Sec.III A 2). $^{43,44,64-67}$ The ground state is obtained by filling the above four bands.

As Eq.(7) contains $U(1)_{1st}$ and an accidental extra $U(1)_{2nd}$ symmetry, we shall ask:

Question 2: "Whether there is a local finite Hamiltonian realizing only a U(1) 3-5-4-0 symmetry as an onsite symmetry with short-range interactions defined on a 1D spatial lattice with a continuous time, such that its low energy physics produces the anomaly-free chiral fermion theory Eq.(2)?"

Yes, by adding a small local perturbation to break $U(1)_{2nd}$ 0-4-5-3 symmetry, we can achieve a faithful $U(1)_{1st}$ 3-5-4-0 symmetry chiral fermion theory of Eq.(2). For example, we can adjust Eq.(7)'s $H \to H + \delta H$ by adding:

$$\delta H = G'_{tiny} \sum_{j \in \mathcal{B}} \left(\left(\hat{f}_3(j)_{pt.s.} \right)^3 \left(\hat{f}_5^{\dagger}(j)_{pt.s.} \right)^1 \left(\hat{f}_4^{\dagger}(j) \right)^1 + h.c. \right)$$

$$\Leftrightarrow \tilde{g}'_{tiny} \left((\tilde{\psi}_{L,3} \nabla_x \tilde{\psi}_{L,3} \nabla_x^2 \tilde{\psi}_{L,3}) (\tilde{\psi}_{R,5}^{\dagger}) (\tilde{\psi}_{L,4}^{\dagger}) + \text{h.c.} \right)$$

$$\Leftrightarrow g'_{tiny} \cos(3\Phi_3^{\text{B}} - \Phi_5^{\text{B}} - \Phi_4^{\text{B}}) \equiv g'_{tiny} \cos(\ell' \cdot \Phi^{\text{B}}).$$

Here we have $\ell'=(3,-1,-1,0)$. The $g'_{tiny}\cos(\ell'\cdot\Phi^{\rm B})$ is not designed to be a gapping term (its self and mutual statistics happen to be nontrivial: $\ell'^T\cdot(K^{\rm B})^{-1}\cdot\ell'\neq 0$, $\ell'^T\cdot(K^{\rm B})^{-1}\cdot\ell_2\neq 0$), but this tiny perturbation term is meant to preserve U(1)_{1st} 3-5-4-0 symmetry only, thus

$$\ell^{\prime T} \cdot \mathbf{t}_1 = \ell^{\prime T} \cdot (K^{\mathbf{B}})^{-1} \cdot \ell_1 = 0$$
 (9)

We must set $(|G_{tiny'}|/|G|) \ll 1$ with $|G_1| \sim |G_2| \sim |G|$ about the same magnitude, so that the tiny local perturbation will not destroy the energy gap (not a usual quadratic mass gap).

Without the interaction, i.e. $G_1 = G_2 = 0$, the edge excitations of the above four bands produce the chiral fermion theory Eq.(2) on the left edge A and the mirror partners on the right edge B. So the total low energy effective theory is non-chiral. In Sec.III A 2, we will provide an explicit lattice model for this free fermion theory.

However, by turning on the intermediate-strength interaction $G_1, G_2 \neq 0$, we claim the interaction terms can fully gap out the edge excitations on the right mirrored edge B as in Fig.2. To find those gapping terms is not accidental - it is guaranteed by our proof (see

Sec.IVB, IVC, Appendix C and D) of equivalence between the anomaly matching condition^{5,57–59} (as $\mathbf{t}_i^T \cdot (K)^{-1} \cdot \mathbf{t}_j = 0$ of Eq.(5)) and the boundary fully gapping rules^{39-42,48,50,52} (here G_1, G_2 terms can gap out the edge) in 1+1 D. The low energy effective theory of the interacting lattice model with only gapless states on the edge A is the chiral fermion theory in Eq.(2). Since the width of the cylinder is finite, the lattice model Eq. (7) is actually a 1+1D lattice model, which gives a non-perturbative lattice definition of the chiral fermion theory Eq.(2). Indeed, the Hamiltonian and the lattice need not to be restricted merely to Eq.(7) and Fig.2, we stress that any on-site symmetry lattice model produces four bands with the desired Chern numbers would work. We emphasize again that the U(1) symmetry is realized as an onsite symmetry^{29,30} in our lattice model. It is easy to gauge such an onsite U(1) symmetry (explained in Appendix B) to obtain a chiral fermion theory coupled to a U(1) gauge field.

III. FROM A CONTINUUM FIELD THEORY TO A DISCRETE LATTICE MODEL

We now comment about the mapping from a continuum field theory of the action Eq.(2) to a discretized space Hamiltonian Eq.(7) with a continuous time. We do not pursue Ginsparg-Wilson scheme, and our gapless edge states are not derived from the discretization of spacetime action. Instead, we will show that the Chern insulator Hamiltonian in Eq.(7) as we described can provide essential gapless edge states for a free theory (without interactions G_1, G_2).

Energy and Length Scales: We consider a finite 1+1D quantum system with a periodic length scale L for the compact circle of the cylinder in Fig.2. The finite size width of the cylinder is w. The lattice constant is a. The energy gap (not a usual quadratic mass gap) we wish to generate on the mirrored edge is Δ_m , which causes a two-point correlator has an exponential decay:

$$\langle \psi^{\dagger}(r)\psi(0)\rangle \sim \langle e^{-\mathrm{i}\Phi(r)}e^{\mathrm{i}\Phi(0)}\rangle \sim \exp(-|r|/\xi)$$
 (10)

with a correlation length scale ξ . The expected length scales follow that

$$a < \xi \ll w \ll L. \tag{11}$$

The 1D system size L is larger than the width w, the width w is larger than the correlation length ξ , the correlation length ξ is larger than the lattice constant a.

A. Free kinetic part and the edge states of a Chern insulator

1. Kinetic part mapping and RG analysis

The **kinetic part** of the lattice Hamiltonian contains the nearest neighbor hopping term $\sum_{\langle i,j\rangle} (t_{ij,q})$

 $\hat{f}_q^{\dagger}(i)\hat{f}_q(j)+h.c.$) together with the next-nearest neighbor hopping term $\sum_{\langle\langle i,j\rangle\rangle} \left(t'_{ij,q}\,\hat{f}_q^{\dagger}(i)\hat{f}_q(j)+h.c.\right)$, which generate the leading order field theory kinetic term via

$$t_{ij}\hat{f}_q^{\dagger}(i)\hat{f}_q(j) \sim a i\psi_q^{\dagger}\partial_x\psi_q + \dots,$$
 (12)

here hopping constants t_{ij}, t'_{ij} with a dimension of energy $[t_{ij}] = [t'_{ij}] = 1$, and a is the lattice spacing with a value [a] = -1. Thus, $[\hat{f}_q(j)] = 0$ and $[\psi_q] = \frac{1}{2}$. The map from

$$f_q \to \sqrt{a} \, \psi_q + \dots$$
 (13)

contains subleading terms. Subleading terms ... potentially contain higher derivative $\nabla^n_x \psi_q$ are only subleading perturbative effects

$$f_q \to \sqrt{a} \left(\psi_q + \dots + a^n \alpha_{\text{small}} \nabla_x^n \psi_q + \dots \right)$$

with small coefficients of the polynomial of the small lattice spacing a via $\alpha_{\rm small} = \alpha_{\rm small}(a) \lesssim (a/L)$. We comment that only the leading term in the mapping is important, the full account for the exact mapping from the fermion operator f_q to ψ_q is immaterial to our model, because of two main reasons:

- •(i) Our lattice construction is based on several layers of Chern insulators, and the chirality of each layer's edge states are protected by a topological number the first Chern number $C_1 \in \mathbb{Z}$. Such an integer Chern number cannot be deformed by small perturbation, thus it is **non-perturbative topologically robust**, hence the chirality of edge states will be protected and will not be eliminated by small perturbations. The origin of our fermion chirality (breaking parity and time reversal) is an emergent phenomena due to the complex hopping amplitude of some hopping constant t'_{ij} or $t_{ij} \in \mathbb{C}$. Beside, it is well-known that Chern insulator can produce the gapless fermion energy spectrum at low energy. More details and the energy spectrum are explicitly presented in Sec.III A 2.
- •(ii) The properly-designed interaction effect (from boundary fully gapping rules) is a **non-perturbative topological effect** (as we will show in Sec.IV C and Appendix E). In addition, we can also do the **weak coupling** and the **strong coupling RG** (renormalization group) analysis to show such subleading-perturbation is *irrelevant*.

For weak-coupling RG analysis, we can start from the free theory fixed point, and evaluate $\alpha_{\text{small}}\psi_q\ldots\nabla_x^n\psi_q$ term, which has a higher energy dimension than $\psi_q^{\dagger}\partial_x\psi_q$, thus irrelevant at the infrared low energy, and irrelevant to the ground state of our Hamiltonian.

For strong-coupling RG analysis at large g_1, g_2 coupling (shown to be the massive phase with energy gap in Sec.IV C and Appendix E), it is convenient to use

the **bosonized language** to map the fermion interaction $U_{\text{interaction}}(\tilde{\psi}_q, \dots, \nabla_x^n \tilde{\psi}_q, \dots)$ of $S_{\Psi_B, interact}$ to boson cosine term $g_a \cos(\ell_{a,I} \cdot \Phi_I)$ of $S_{\Phi_{interact}}$. At the large g coupling fixe point, the boson field is pinned down at the minimum of cosine potential, we thus will consider the dominant term as the discretized spatial lattice (a site index j) and only a continuous time: $\int dt \left(\sum_j \frac{1}{2} g(\ell_{a,I} \cdot \Phi_{I,j})^2 + \ldots\right).$ Setting this dominant term to be a marginal operator means the scaling dimension of $\Phi_{I,j}$ is $[\Phi_{I,j}] = 1/2$ at strong coupling fixed point. Since the kinetic term is generated by an operator:

$$e^{iP_{\Phi}a} \sim e^{ia\partial_x \Phi} \sim e^{i(\Phi_{j+1} - \Phi_j)}$$

where $e^{\mathrm{i}P_{\Phi}a}$ generates the lattice translation by $e^{\mathrm{i}P_{\Phi}a}\Phi e^{-\mathrm{i}P_{\Phi}a}=\Phi+a$, but $e^{\mathrm{i}\Phi}$ containing higher powers of irrelevant operators of $(\Phi_I)^n$ for n>2, thus the kinetic term is an irrelevant operator at the strong-coupling massive fixed point.

The higher derivative term $\alpha_{\text{small}} \psi_q \dots \nabla_x^n \psi_q$ is generated by the further long range hopping, thus contains higher powers of : $e^{i\Phi}$: thus this subleading terms in Eq. (13) are further irrelevant perturbation at the infrared, comparing to the dominant cosine terms. Further details of weak, strong coupling RG are presented in Appendix E 3.

2. Numerical simulation for the free fermion theory with nontrivial Chern number

Follow from Sec.II and III A 1, here we provide a concrete lattice realization for free fermions part of Eq.(7) (with $G_1 = G_2 = 0$), and show that the Chern insulator provides the desired gapless fermion energy spectrum (say, a left-moving Weyl fermion on the edge A and a right-moving Weyl fermion on the edge B, and totally a Dirac fermion for the combined). We adopt the chiral π -flux square lattice model⁴⁵ in Fig.3 as an example. This lattice model can be regarded as a free theory of 3-5-4-0 fermions of Eq.(2) with its mirrored conjugate. We will explicitly show filling the first Chern number⁴³ $C_1 = -1$ band of the lattice on a cylinder would give the edge states of a free fermion with U(1) charge 3, similar four copies of model together render 3-5-4-0 free fermions theory of Eq.(7).

We design hopping constants $t_{ij,3} = t_1 e^{\mathrm{i}\pi/4}$ along the black arrow direction in Fig.3, and its hermitian conjugate determines $t_{ij,3} = t_1 e^{-\mathrm{i}\pi/4}$ along the opposite hopping direction; $t'_{ij,3} = t_2$ along dashed brown links, $t'_{ij,3} = -t_2$ along dotted brown links. The shaded blue region in Fig.3 indicates a unit cell, containing two sublattice as a black dot a and a white dot b. If we put the lattice model on a torus with periodic boundary conditions for both x, y directions, then we can write the Hamiltonian in $\mathbf{k} = (k_x, k_y)$ space in Brillouin zone (BZ), as $H = \sum_{\mathbf{k}} f^{\dagger}_{\mathbf{k}} H(\mathbf{k}) f_{\mathbf{k}}$, where $f_{\mathbf{k}} = (f_{a,\mathbf{k}}, f_{b,\mathbf{k}})$. For two sublattice a, b, we have a generic pseudospin form

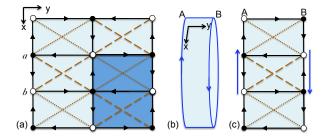

FIG. 3: Chiral π -flux square lattice: (a) A unit cell is indicated as the shaded darker region, containing two sublattice as a black dot a and a white dot b. The lattice Hamiltonian has hopping constants, $t_1e^{i\pi/4}$ along the black arrow direction, t_2 along dashed brown links, $-t_2$ along dotted brown links. (b) Put the lattice on a cylinder. (c) The ladder: the lattice on a cylinder with a square lattice width. The chirality of edge state is along the direction of blue arrows.

of Hamiltonian $H(\mathbf{k})$,

$$H(\mathbf{k}) = B_0(\mathbf{k}) + \vec{B}(\mathbf{k}) \cdot \vec{\sigma}. \tag{14}$$

 $\vec{\sigma}$ are Pauli matrices $(\sigma_x, \sigma_y, \sigma_z)$. In this model $B_0(\mathbf{k}) = 0$ and $\vec{B} = (B_x(\mathbf{k}), B_y(\mathbf{k}), B_z(\mathbf{k}))$ have three components in terms of \mathbf{k} and lattice constants a_x, a_y . The eigenenergy E_{\pm} of $H(\mathbf{k})$ provide two nearly-flat energy bands, shown in Fig.4, from $H(\mathbf{k})|\psi_{\pm}(\mathbf{k})\rangle = E_{\pm}|\psi_{\pm}(\mathbf{k})\rangle$.

For the later purpose to have the least mixing between edge states on the left edge A and right edge B on a cylinder in Fig.3(b), here we fine tune $t_2/t_1=1/2$. For convenience, we simply set $t_1=1$ as the order magnitude of E_{\pm} . We set lattice constants $a_x=1/2, a_y=1$ such that BZ has $-\pi \le k_x < \pi, -\pi \le k_y < \pi$. The first Chern number⁴³ of the energy band $|\psi_{+}(\mathbf{k})\rangle$ is

$$C_1 = \frac{1}{2\pi} \int_{\mathbf{k} \in BZ} d^2 \mathbf{k} \; \epsilon^{\mu\nu} \partial_{k_{\mu}} \langle \psi(\mathbf{k}) | -i \partial_{k_{\nu}} | \psi(\mathbf{k}) \rangle. \tag{15}$$

We find $C_{1,\pm}=\pm 1$ for two bands. The $C_{1,-}=-1$ lower energy band indicates the clockwise chirality of edge states when we put the lattice on a cylinder as in Fig.3(b). Overall it implies the chirality of the edge state on the left edge A moving along $-\hat{x}$ direction, and on the right edge B moving along $+\hat{x}$ direction - the clockwise chirality as in Fig.3(b), consistent with the earlier

result $C_{1,-} = -1$ of Chern number. This edge chirality is demonstrated in Fig.5. Details are explained in its captions and in Appendix F 1.

The above construction is for edge states of free fermion with U(1) charge 3 of 3_L - 5_R - 4_L - 0_R fermion model. Add the same copy with $C_{1,-} = -1$ lower band gives another layer of U(1) charge 4 free fermion. For another layers of U(1) charge 5 and 0, we simply adjust hopping constant t_{ij} to $t_1e^{-i\pi/4}$ along the black arrow direction and $t_1e^{i\pi/4}$ along the opposite direction in Fig.3, which makes $C_{1,-} = +1$. Stack four copies of chiral π -flux ladders with $C_{1,-} = -1, \pm 1, -1, +1$ provides the

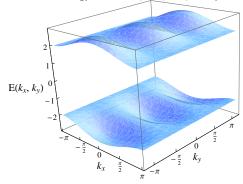

FIG. 4: Two nearly-flat energy bands E_{\pm} in Brillouin zone for the kinetic hopping terms of our model Eq.(7).

lattice model of 3-5-4-0 free fermions with its mirrored conjugate.

The lattice model so far is an effective 1+1D non-chiral theory. We claim the interaction terms $(G_1, G_2 \neq 0)$ can gap out the mirrored edge states on the edge B. The simulation including interactions can be numerically expansive, even so on a simple ladder model. Because of higher power interactions, one can no longer diagonalize the model in \mathbf{k} space as the case of the quadratic free-fermion Hamiltonian. For interacting case, one may need to apply exact diagonalization in real space, or density matrix renormalization group (DMRG⁶⁸), which is powerful in 1+1D. We leave this interacting numerical study for the lattice community or the future work.

B. Interaction gapping terms and the strong coupling scale

Similar to Sec.III A 1, for the interaction gapping terms of the Hamiltonian, we can do the mapping based

on Eq.(13), where the leading terms on the lattice is

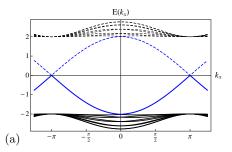

$$g_{a} \cos(\ell_{a,I} \cdot \Phi_{I})$$

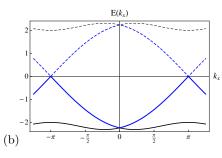

$$= U_{\text{interaction}}(\tilde{\psi}_{q}, \dots, \nabla_{x}^{n} \tilde{\psi}_{q}, \dots))$$

$$\to U_{\text{point.split.}}(\hat{f}_{q}(j), \dots (\hat{f}_{q}^{n}(j))_{pt.s.}, \dots)$$

$$+\alpha_{\text{small}} \dots$$

$$(16)$$

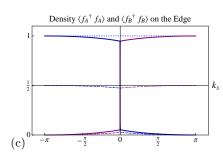

FIG. 5: The energy spectrum $E(k_x)$ and the density matrix $\langle f^\dagger f \rangle$ of the chiral π -flux model on a cylinder: (a) On a 10-sites width $(9a_y$ -width) cylinder: The blue curves are edge states spectrum. The black curves are for states extending in the bulk. The chemical potential at zero energy fills eigenstates in solid curves, and leaves eigenstates in dashed curves unfilled. (b) On the ladder, a 2-sites width $(1a_y$ -width) cylinder: the same as the (a)'s convention. (c) The density $\langle f^\dagger f \rangle$ of the edge eigenstates (the solid blue curve in (b)) on the ladder lattice. The dotted blue curve shows the total density sums to 1, the darker purple curve shows $\langle f_A^\dagger f_A \rangle$ on the left edge A, and the lighter purple curve shows $\langle f_B^\dagger f_B \rangle$ on the right edge B. The dotted darker(or lighter) purple curve shows density $\langle f_{A,a}^\dagger f_{A,a} \rangle$ (or $\langle f_{B,a}^\dagger f_{B,a} \rangle$) on sublattice a, while the dashed darker(or lighter) purple curve shows density $\langle f_{A,b}^\dagger f_{A,b} \rangle$ (or $\langle f_{B,b}^\dagger f_{B,b} \rangle$) on sublattice b. This edge eigenstate has the left edge A density with majority quantum number $k_x < 0$, and has the right edge B density with majority quantum number $k_x > 0$. Densities on two sublattice a, b are equally distributed as we desire.

Note: Here we do not use the domain wall fermion approach, and we do not require a 1D domain wall in an infinite large 2D lattice system. We cannot overly emphasize that our 1D spatial lattice model (effectively 1D ladder, or a 2D cylinder with finite width along y, here we focus on the quadratic free part of Hamiltonian in Eq. (7)) with a finite Hilbert space can already effectively simulate the relativistic 1+1D doubling Weyl fermion theory at low energy.

Again, potentially there may contain subleading pieces, such as further higher order derivatives $\alpha_{\text{small}} \nabla_x^n \psi_q$ with a small coefficient α_{small} , or tiny mixing of the different U(1)-charge flavors $\alpha'_{\text{small}} \psi_{q_1} \psi_{q_2} \dots$ However, using the same RG analysis in Sec.III A 1, at both the weak coupling and the strong coupling fix points, we learn that those α_{small} terms are only **subleading-perturbative effects** which are further irrelevant perturbation at the infrared comparing to the dominant piece (which is the kinetic term for the weak g coupling, but is replaced by

the cosine term for the strong q coupling).

One more question to ask is: what is the scale of coupling G such that the gapping term becomes dominant and the B edge states form the energy gaps, but maintaining (without interfering with) the gapless A edge states?

To answer this question, we first know the absolute value of energy magnitude for each term in the desired Hamiltonian for our chiral fermion model:

 $|G \text{ gapping term}| \gtrsim |t_{ij}, t'_{ij}|$ kinetic term $|\gg |G \text{ higher order } \nabla_x^n \text{ and mixing terms}| \gg |t_{ij}, t'_{ij}|$ higher order $\psi_q \dots \nabla_x^n \psi_q |$. (17)

For **field theory**, the gapping terms (the cosine potential term or the multi-fermion interactions) are irrelevant for a weak g coupling, this implies that g needs to be large enough. Here the $g \equiv (g_a)/a^2$ really means the dimensionless quantity g_a .

For lattice model, however, the dimensional analysis is very different. Since the G coupling of gapping terms and the hopping amplitude t_{ij} both have dimension of energy $[G] = [t_{ij}] = 1$, this means that the scale of the dimensionless quantity of $|G|/|t_{ij}|$ is important. (The $|t_{ij}|, |t'_{ij}|$ are about the same order of magnitude.)

Presumably we can design the lattice model under Eq.(11), $a < \xi < w < L$, such that their ratios between each length scale are about the same. We expect the ratio of couplings of |G| to $|t_{ij}|$ is about the ratio of energy

gap Δ_m to kinetic energy fluctuation δE_k caused by t_{ij} hopping, thus very roughly

$$\frac{|G|}{|t_{ij}|} \sim \frac{\Delta_m}{\delta E_k} \sim \frac{(\xi)^{-1}}{(w)^{-1}} \sim \frac{w}{\xi} \sim \frac{L}{w} \sim \frac{\xi}{a}.$$
 (18)

We expect that the scales at strong coupling G is about

$$|G| \gtrsim |t_{ij}| \cdot \frac{\xi}{a} \tag{19}$$

this magnitude can support our lattice chiral fermion model with mirror-fermion decoupling. If G is too much smaller than $|t_{ij}| \cdot \frac{\xi}{a}$, then mirror sector stays gapless. On the other hand, if $|G|/|t_{ij}|$ is too much stronger or simply $|G|/|t_{ij}| \to \infty$ may cause either of two disastrous cases:

(i) Both edges would be gapped and the whole 2D plane becomes dead without kinetic hopping, if the correlation length reaches the scale of the cylinder width: $\xi \geq w$.

(ii) The B edge (say at site $n\hat{y}$) becomes completely gapped, but forms a dead overly-high-energy 1D line decoupled from the remain lattice. The neighbored line (along $(n-1)\hat{y}$) next to edge B experiences no interaction thus may still form mirror gapless states near B. (This may be another reason why CGP fails in Ref.25 due to implementing overlarge strong coupling.)

So either the two cases caused by too much strong $|G|/|t_{ij}|$ is not favorable. Only $|G| \gtrsim |t_{ij}| \cdot \frac{\xi}{a}$, we can have the mirrored sector at edge B gapped, meanwhile keep the chiral sector at edge A gapless. $\frac{|G|}{|t_{ij}|}$ is somehow larger than order 1 is what we referred as the **intermediate(-strong)** coupling.

$$\frac{|G|}{|t_{ij}|} \gtrsim O(1). \tag{20}$$

(Our O(1) means some finite values, possibly as large as $10^4, 10^6$, etc, but still finite. And the kinetic term is *not* negligible.) The sign of G coupling shall not matter, since in the cosine potential language, either g_1, g_2 greater or smaller than zero are related by sifting the minimum energy vaccua of the cosine potential.

To summarize, the two key messages in Sec.III are:

- First, the free-kinetic hopping part of lattice model has been simulated and there gapless energy spectra have been computed shown in Figures. The energy spectra indeed show the gapless Weyl fermions on each edge. So, the continuum field theory to a lattice model mapping is immaterial to the subleading terms of Eq.(13), the physics is as good or as exact as we expect for the free kinetic part. We comment that this lattice realization of quantum hall-like states with chiral edges have been implemented for long in condensed matter, dated back as early such as Haldane's work.⁴⁴
- Second, by adding the interaction gapping terms, the spectra will be modified from the mirror gapless edge to the mirror gapped edge. The continuum field theory to a lattice model mapping based on Eq.(13) for the gapping terms in Eq.(16) is as good or as exact as the free kinetic part Eq.(12), because the mapping is the same procedure as in Eq.(13). Since the subleading correction for the free and for the interacting parts are further irrelevant perturbation at the infrared, the non-perturbative topological effect of the gapped edge contributed from the leading terms remains.

In the next section, we will provide a **topological** non-perturbative proof to justify that the G_1, G_2 interaction terms can gap out mirrored edge states, without employing numerical methods, but purely based on an analytical derivation.

IV. TOPOLOGICAL NON-PERTURBATIVE PROOF OF ANOMALY MATCHING CONDITIONS = BOUNDARY FULLY GAPPING RULES

As Sec. II and III prelude, we now show that Eq.(7) indeed gaps out the mirrored edge states on the edge B in Fig.2. This proof will support the evidence that Eq.(7) gives the non-perturbative lattice definition of the 1+1D chiral fermion theory of Eq.(2).

In Sec.IV A, we first provide a generic way to formulate our model, with a insulating bulk but with gapless edge states. This can be done through so called the **bulk-edge correspondence**, namely the Chern-Simons theory in the bulk and the Wess-Zumino-Witten (WZW) model on the boundary. More specifically, for our case with U(1) symmetry chiral matter theory, we only needs a $U(1)^N$ rank-N Abelian K matrix Chern-Simons theory in the bulk and the multiplet chiral boson theory on the boundary. We can further fermionize the multiplet chiral boson theory to the multiplet chiral fermion theory.

In Sec.IVB, we provide a physical understanding between the anomaly matching conditions and the effective Hall conductance. This intuition will be helpful to understand the relation between the anomaly matching conditions and Boundary Fully Gapping Rules, to be discussed in Sec.IV C.

A. Bulk-Edge Correspondence - 2+1D Bulk Abelian SPT by Chern-Simons theory

With our 3_L - 5_R - 4_L - 0_R chiral fermion model in mind, below we will trace back to fill in the background how we obtain this model from the understanding of symmetry-protected topological states (SPT). This understanding in the end leads to a more general construction.

We first notice that the bosonized action of the free part of chiral fermions in Eq.(4), can be regarded as the edge states action S_{∂} of a bulk $\mathrm{U}(1)^N$ Abelian K matrix Chern-Simons theory S_{bulk} (on a 2+1D manifold \mathcal{M} with the 1+1D boundary $\partial \mathcal{M}$):

$$S_{bulk} = \frac{K_{IJ}}{4\pi} \int_{\mathcal{M}} a_I \wedge da_J = \frac{K_{IJ}}{4\pi} \int_{\mathcal{M}} dt \, d^2 x \varepsilon^{\mu\nu\rho} a_\mu^I \partial_\nu a_\rho^J,$$
(21)

$$S_{\partial} = \frac{1}{4\pi} \int_{\partial \mathcal{M}} dt \ dx \ K_{IJ} \partial_t \Phi_I \partial_x \Phi_J - V_{IJ} \partial_x \Phi_I \partial_x \Phi_J.$$
(22)

Here a_{μ} is intrinsic 1-form gauge field from a low energy viewpoint. Both indices I, J run from 1 to N. Given K_{IJ} matrix, it is known the ground state degeneracy (GSD) of this theory on the \mathbb{T}^2 torus is GSD = $|\det K|$. 41,71 V_{IJ} is the symmetric 'velocity' matrix, we can simply choose $V_{IJ} = \mathbb{I}$, without losing generality of our argument. The U(1) N gauge transformation is $a_I \to a_I + df_I$ and $\Phi_I \to \Phi_I + f_I$. The bulk-edge correspondence is meant to have the gauge non-invariances of the bulk-only

and the edge-only cancel with each other, so that the total gauge invariances is achieved from the full bulk and edge as a whole.

We will consider only an even integer $N \in 2\mathbb{Z}^+$. The reason is that only such even number of edge modes, we can potentially gap out the edge states. (For odd integer N, such a set of gapping interaction terms generically do not exist, so the mirror edge states remain gapless.)

To formulate 3_L - 5_R - 4_L - 0_R fermion model, as shown in Eq.(4), we need a rank-4 K matrix $\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \oplus \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$. Generically, for a general U(1) chiral fermion model, we can use a canonical fermionic matrix

$$K_{N\times N}^f = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \oplus \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \oplus \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \oplus \dots$$
 (23)

Such a matrix is special, because it describes a more-restricted Abelian Chern-Simons theory with GSD= $|\det K_{N\times N}^f|=1$ on the \mathbb{T}^2 torus. In the condensed matter language, the uniques GSD implies it has no long range entanglement, and it has no intrinsic topological order. Such a state may be wronged to be only a trivial insulator, but actually this is recently-known to be potentially nontrivial as the symmetry-protected topological states (SPT).

(This paragraph is for readers with interests in SPT: SPT are short-range entangled states with onsite symmetry in the bulk.²⁹ For SPT, there is no long-range entanglement, no fractionalized quasiparticles (fractional anyons) and no fractional statistics in the bulk.²⁹ The bulk onsite symmetry may be realized as a non-onsite symmetry on the boundary. If one gauges the non-onsite symmetry of the boundary SPT, the boundary theory becomes an anomalous gauge theory.²⁸ The anomalous gauge theory is ill-defined in its own dimension, but can be defined as the boundary of the bulk SPT. However, this understanding indicates that if the boundary theory happens to be anomaly-free, then it can be defined non-perturbatively on the same dimensional lattice.)

 $K_{N\times N}^f$ matrix describe **fermionic SPT states**, which is described by bulk *spin Chern-Simons theory* of $|\det K|=1$. A spin Chern-Simons theory only exist on the spin manifold, which has spin structure and can further define spinor bundles. ⁹³ However, there are another simpler class of SPT states, the **bosonic SPT states**, which is described by the canonical form $K_{N\times N}^{b\pm}$ ^{41,72,73} with blocks of $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and a set of all positive(or negative) coefficients E_8 lattices K_{E_8} , ^{41,50,51,72} namely,

$$K_{N\times N}^{b0} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \oplus \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \oplus \dots$$

$$K_{N\times N}^{b\pm} = K^{b0} \oplus (\pm K_{E_8}) \oplus (\pm K_{E_8}) \oplus \dots$$
(24)

The $K_{\rm E_8}$ matrix describe 8-multiplet chiral bosons moving in the same direction, thus it cannot be gapped by adding multi-fermion interaction among themselves. We will neglect $\rm E_8$ chiral boson states but only focus on $K_{N\times N}^{b0}$ for the reason to consider only the gappable states. The K-matrix form of Eq.(23),(24) is called the unimodular indefinite symmetric integral matrix.

After fermionizing the boundary action Eq.(22) with $K_{N\times N}^f$ matrix, we obtain multiplet chiral fermions (with several pairs, each pair contain left-right moving Weyl fermions forming a Dirac fermion).

$$S_{\Psi} = \int_{\partial \mathcal{M}} dt \ dx \ (i\bar{\Psi}_{\mathcal{A}} \Gamma^{\mu} \partial_{\mu} \Psi_{\mathcal{A}}). \tag{25}$$

with
$$\Gamma^0 = \bigoplus_{j=1}^{N/2} \gamma^0$$
, $\Gamma^1 = \bigoplus_{j=1}^{N/2} \gamma^1$, $\Gamma^5 \equiv \Gamma^0 \Gamma^1$, $\bar{\Psi}_i \equiv \Psi_i \Gamma^0$
and $\gamma^0 = \sigma_x$, $\gamma^1 = i\sigma_y$, $\gamma^5 \equiv \gamma^0 \gamma^1 = -\sigma_z$.

Symmetry transformation for the edge states-

The edge states of $K_{N\times N}^f$ and $K_{N\times N}^{b0}$ Chern-Simons theory are non-chiral in the sense there are equal number of left and right moving modes. However, we can make them with a charged 'chirality' respect to a global(or external probed, or dynamical gauge) symmetry group. For the purpose to build up our 'chiral fermions and chiral bosons' model with 'charge chirality,' we consider the simplest possibility to couple it to a global U(1) symmetry with a charge vector \mathbf{t} . (This is the same as the symmetry charge vector of SPT states 50,52,73)

Chiral Bosons: For the case of multiplet chiral boson theory of Eq.(22), the group element g_{θ} of U(1) symmetry acts on chiral fields as

$$g_{\theta}: W^{\mathrm{U}(1)_{\theta}} = \mathbb{I}_{N \times N}, \ \delta \phi^{\mathrm{U}(1)_{\theta}} = \theta \mathbf{t},$$
 (26)

With the following symmetry transformation,

$$\phi \to W^{\mathrm{U}(1)_{\theta}} \phi + \delta \phi^{\mathrm{U}(1)_{\theta}} = \phi + \theta \mathbf{t}$$
 (27)

To derive this boundary symmetry transformation from the bulk Chern-Simons theory via bulk-edge correspondence, we first write down the charge coupling bulk Lagrangian term, namely $\frac{\mathbf{q}^I}{2\pi} \; \epsilon^{\mu\nu\rho} A_\mu \partial_\nu a^I_\rho$, where the global symmetry current $\mathbf{q}^I J^{I\mu} = \frac{\mathbf{q}^I}{2\pi} \; \epsilon^{\mu\nu\rho} \partial_\nu a^I_\rho$ is coupled to an external gauge field A_μ . The bulk U(1)-symmetry current $\mathbf{q}^I J^{I\mu}$ induces a boundary U(1)-symmetry current $\mathbf{q}^I j^{I\mu} = \frac{\mathbf{q}^I}{2\pi} \; \epsilon^{\mu\nu} \partial_\nu \phi_I$. This implies the boundary symmetry operator is $S_{sym} = \exp(\mathrm{i} \; \theta \; \frac{\mathbf{q}^I}{2\pi} \int \partial_x \phi_I)$, with an arbitrary U(1) angle θ The induced symmetry transformation on ϕ_I is:

$$(S_{sym})\phi_I(S_{sym})^{-1} = \phi_I - i\theta \int dx \frac{\mathbf{q}^l}{2\pi} [\phi_I, \partial_x \phi_l]$$
$$= \phi_I + \theta(K^{-1})_{Il} \mathbf{q}^l \equiv \phi_I + \theta \mathbf{t}_I, \tag{28}$$

here we have used the canonical commutation relation $[\phi_I, \partial_x \phi_I] = i2\pi (K^{-1})_{Il}$. Compare the two Eq.(27),(28), we learn that

$$\mathbf{t}_I \equiv (K^{-1})_{Il} \mathbf{q}^l$$
.

The charge vectors \mathbf{t}_I and \mathbf{q}^l are related by an inverse of the K matrix. The generic interacting or gapping

terms 41,42,50 for the multiplet chiral boson theory are the sine-Gordon or the cosine term

$$S_{\partial,\text{gap}} = \int dt \ dx \ \sum_{a} g_a \cos(\ell_{a,I} \cdot \Phi_I).$$
 (29)

If we insist that $S_{\partial,\text{gap}}$ obeys U(1) symmetry, to make Eq.(29) invariant under Eq.(28), we have to impose

$$\ell_{a,I} \cdot \Phi_I \to \ell_{a,I} \cdot (\Phi_I + \delta \phi^{\mathrm{U}(1)_{\theta}}) \bmod 2\pi$$
so $\ell_{a,I} \cdot \mathbf{t}_I = 0$ (30)

$$\Rightarrow \boxed{\ell_{a,I} \cdot (K^{-1})_{Il} \cdot \mathbf{q}^l = 0}.$$
 (31)

The above generic U(1) symmetry transformation works for bosonic $K_{N\times N}^{b0}$ as well as fermionic $K_{N\times N}^{f}$.

Chiral Fermions: In the case of fermionic $K_{N\times N}^f$, we will do one more step to fermionize the multiplet chiral boson theory. Fermionize the free kinetic part from Eq.(22) to Eq.(25), as well as the interacting cosine term:

$$g_a \cos(\ell_{a,I} \cdot \Phi_I)$$

$$\to \prod_{I=1}^N \tilde{g}_a ((\psi_{q_I})(\nabla_x \psi_{q_I}) \dots (\nabla_x^{|\ell_{a,I}|-1} \psi_{q_I}))^{\epsilon}$$

$$\equiv U_{\text{interaction}} (\psi_q, \dots, \nabla_x^n \psi_q, \dots)$$
(32)

to multi-fermion interaction. The ϵ is defined as the complex conjugation operator which depends on $\operatorname{sgn}(\ell_{a,I})$, the sign of $\ell_{a,I}$. When $\operatorname{sgn}(\ell_{a,I}) = -1$, we define $\psi^{\epsilon} \equiv \psi^{\dagger}$ and also for the higher power polynomial terms. Again, we absorb the normalization factor and the Klein factors through normal ordering of bosonization into the factor \tilde{g}_a . The precise factor is not of our concern, since our goal is a non-perturbative lattice model. Obviously, the U(1) symmetry transformation for fermions is

$$\psi_{q_I} \to \psi_{q_I} e^{i\mathbf{t}_I \theta} = \psi_{q_I} e^{i(K^{-1})_{Il} \cdot \mathbf{q}^l \cdot \theta}$$
 (33)

In summary, we have shown a framework to describe U(1) symmetry chiral fermion/boson model using the bulk-edge correspondence, the explicit Chern-Siomns/WZW actions are given in Eq.(21),(22),(25),(29),(32), and their symmetry realization Eq.(28),(33) and constrain are given in Eq.(30),(31). Their physical properties are tightly associated to the fermionic/bosonic SPT states.

B. Anomaly Matching Conditions and Effective Hall Conductance

The bulk-edge correspondence is meant, not only to achieve the gauge invariance by canceling the non-invariance of bulk-only and boundary-only, but also to have the boundary anomalous current flow can be transported into the extra dimensional bulk. This is known as Callan-Harvey effect⁷⁶ in high energy physics, Laughlin

thought experiment,⁷⁸ or simply the quantum-hall-like state bulk-edge correspondence in condensed matter theory.

The goal of this subsection is to provide a concrete physical understanding of the anomaly matching conditions and effective Hall conductance:

• (i) The anomalous current inflowing from the boundary is transported into the bulk. We now show that this thinking can easily derive the 1+1D U(1) Adler-Bell-Jackiw(ABJ) anomaly, or Schwinger's 1+1D quantum electrodynamics(QED) anomaly.

We will focus on the U(1) chiral anomaly, which is ABJ anomaly 74,75 type. It is well-known that ABJ anomaly can be captured by the anomaly factor $\mathcal A$ of the 1-loop polygon Feynman diagrams (see Fig.6). The anomaly matching condition requires

$$\mathcal{A} = \operatorname{tr}[T^a T^b T^c \dots] = 0. \tag{34}$$

Here T^a is the (fundamental) representation of the global or gauge symmetry algebra, which contributes to the vertices of 1-loop polygon Feynman diagrams.

For example, the 3+1D chiral anomaly 1-loop triangle diagram of U(1) symmetry in Fig.6(a) with chiral fermions on the loop gives $\mathcal{A} = \sum (q_L^3 - q_R^3)$. Similarly, the 1+1D chiral anomaly 1-loop diagram of U(1) symmetry in Fig.6(b) with chiral fermions on the loop gives $\mathcal{A} = \sum (q_L^2 - q_R^2)$. Here L, R stand for left-moving and right-moving modes.

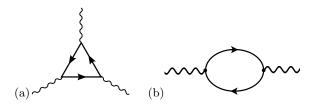

FIG. 6: Feynman diagrams with solid lines representing chiral fermions and wavy lines representing U(1) gauge bosons: (a) 3+1D chiral fermionic anomaly shows $\mathcal{A} = \sum_q (q_L^3 - q_R^3)$ (b) 1+1D chiral fermionic anomaly shows $\mathcal{A} = \sum_q (q_L^2 - q_R^2)$

How to derive this anomaly matching condition from a condensed matter theory viewpoint? Conceptually, we understand that

A d-dimensional anomaly free theory (which satisfies the anomaly matching condition) means that there is no anomalous current leaking from its d-dimensional spacetime (as the boundary) to an extended bulk theory of d+1-dimension.

More precisely, for an 1+1D U(1) anomalous theory realization of the above statement, we can formulate it as the boundary of a 2+1D bulk as in Fig.7 with a Chern-Simons action $(S = \int \left(\frac{K}{4\pi} \ a \wedge da + \frac{q}{2\pi} A \wedge da\right))$. Here the field strength F = dA is equivalent to the external U(1) flux in the Laughlin's flux-insertion thought

Quantum Hall or SPT State

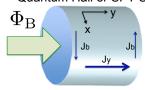

FIG. 7: A physical picture illustrates how the anomalous current J of the boundary theory along x direction leaks to the extended bulk system along y direction. Laughlin flux insertion $d\Phi_B/dt = -\oint E \cdot dL$ induces the electric E_x field along the x direction. The effective Hall effect shows $J_y = \sigma_{xy} E_x = \sigma_{xy} \varepsilon^{\mu\nu} \partial_\mu A_\nu$, with the effective Hall conductance σ_{xy} probed by an external U(1) gauge field A. The anomaly-free condition implies no anomalous bulk current, so $J_y = 0$ for any flux Φ_B or any E_x , thus we derive the anomaly-free condition must be $\sigma_{xy} = 0$.

experiment⁷⁸ threading through the cylinder (see a precise derivation in the Appendix of Ref.38). Without losing generality, let us first focus on the boundary action of Eq.(22) as a chiral boson theory with only one edge mode. We derive its equations of motion as

$$\partial_{\mu} j_{\rm b}^{\mu} = \frac{\sigma_{xy}}{2} \varepsilon^{\mu\nu} F_{\mu\nu} = \sigma_{xy} \varepsilon^{\mu\nu} \partial_{\mu} A_{\nu} = J_{y}, \tag{35}$$

$$\partial_{\mu} j_{\rm L} = \partial_{\mu} (\frac{q}{2\pi} \epsilon^{\mu\nu} \partial_{\nu} \Phi) = \partial_{\mu} (q \bar{\psi} \gamma^{\mu} P_{\rm L} \psi) = +J_{y}, \tag{36}$$

$$\partial_{\mu} j_{\rm R} = -\partial_{\mu} (\frac{q}{2\pi} \epsilon^{\mu\nu} \partial_{\nu} \Phi) = \partial_{\mu} (q \bar{\psi} \gamma^{\mu} P_{\rm R} \psi) = -J_{y} (37)$$

Here we derive the Hall conductance, easily obtained from its definitive relation $J_y = \sigma_{xy} E_x$ in Eq.(35), as⁵⁵

$$\sigma_{xy} = qK^{-1}q/(2\pi).$$

Here $j_{\rm b}$ stands for the edge current, with a left-moving current $j_L=j_{\rm b}$ on one edge and a right-moving current $j_R=-j_{\rm b}$ on the other edge, as in Fig.7. We convert a compact bosonic phase Φ to the fermion field ψ by bosonization. We can combine currents $j_{\rm L}+j_{\rm R}$ as the vector current $j_{\rm V}$, then find its ${\rm U}(1)_V$ current conserved. We combine currents $j_{\rm L}-j_{\rm R}$ as the axial current $j_{\rm A}$, then we obtain the famous ABJ ${\rm U}(1)_A$ anomalous current in 1+1D (or Schwinger 1+1D QED anomaly).

$$\partial_{\mu} j_{V}^{\mu} = \partial_{\mu} (j_{L}^{\mu} + j_{R}^{\mu}) = 0,$$
 (38)

$$\partial_{\mu} j_{\rm A}^{\mu} = \partial_{\mu} (j_{\rm L}^{\mu} - j_{\rm R}^{\mu}) = \sigma_{xy} \varepsilon^{\mu\nu} F_{\mu\nu}. \tag{39}$$

This simple physical derivation shows that the left and right edges' boundary theories (living on the edge of a 2+1D U(1) Chern-Simons theory) can combine to be a 1+1D anomalous world of Schwinger's 1+1D QED.

In other words, when the anomaly-matching condition holds ($\mathcal{A}=0$), then there is no anomalous leaking current into the extended bulk theory,⁷⁶ as in Fig.7, so no 'effective Hall conductance' for this anomaly-free theory.⁷⁷

It is straightforward to generalize the above discussion to a rank-N K matrix Chern-Simons theory. It is easy

to show that the Hall conductance in a 2+1D system for a generic K matrix is (via $\mathbf{q}_l = K_{II} \mathbf{t}_I$)

$$\sigma_{xy} = \frac{1}{2\pi} \mathbf{q} \cdot K^{-1} \cdot \mathbf{q} = \frac{1}{2\pi} \mathbf{t} \cdot K \cdot \mathbf{t}.$$
 (40)

For a 2+1D fermionic system for K^f matrix of Eq.(23),

$$\sigma_{xy} = \frac{q^2}{2\pi} \mathbf{t}(K_{N\times N}^f) \mathbf{t} = \frac{1}{2\pi} \sum_{q} (q_L^2 - q_R^2) = \frac{1}{2\pi} \mathcal{A}.$$
 (41)

Remarkably, this physical picture demonstrates that we can reverse the logic, starting from the 'effective Hall conductance of the bulk system' to derive the anomaly factor from the relation

$$\Delta \text{ (anomaly factor)} = 2\pi\sigma_{xy} \text{ (effective Hall conductance)}$$
(42)

And from the "no anomalous current in the bulk" means that " $\sigma_{xy}=0$ ", we can further understand "the anomaly matching condition $\mathcal{A}=2\pi\sigma_{xy}=0$."

For the U(1) symmetry case, we can explicitly derive the anomaly matching condition for fermions and bosons:

Anomaly Matching Conditions for 1+1D chiral fermions with U(1) symmetry

$$\mathcal{A} = 2\pi\sigma_{xy} = q^2 \mathbf{t}(K_{N\times N}^f)\mathbf{t} = \sum_{i=1}^{N/2} (q_{L,j}^2 - q_{R,j}^2) = 0.$$
(43)

Anomaly Matching Conditions for 1+1D chiral bosons with U(1) symetry

$$\mathcal{A} = 2\pi\sigma_{xy} = q^2 \mathbf{t}(K_{N\times N}^{b0})\mathbf{t} = \sum_{i=1}^{N/2} 2q_{L,j}q_{R,j} = 0.$$
 (44)

Here $q\mathbf{t} \equiv (q_{L,1}, q_{R,1}, q_{L,2}, q_{R,2}, \dots, q_{L,N/2}, q_{R2,N/2})$. (For a bosonic theory, we note that the bosonic charge for this theory is described by non-chiral Luttinger liquids. One should identify the left and right moving charge as $q'_L \propto q_L + q_R$ and $q'_R \propto q_L - q_R$.)

C. Anomaly Matching Conditions and Boundary Fully Gapping Rules

This subsection is the main emphasis of our work, and we encourage the readers paying extra attentions on the result presented here. We will first present a heuristic physical argument on the rules that under what situations the boundary states can be gapped, named as the **Boundary Fully Gapping Rules**. We will then provide a topological non-perturbative proof using the notion of Lagrangian subgroup and the exact sequence, following our previous work Ref.41 and the work in Ref.42,46. And we will also provide perturbative RG analysis, both for strong and weak coupling analysis of cosine potential cases.

1. Physical picture

Here is the physical intuition: To define a topological gapped boundary conditions, it means that the energy spectrum of the edge states are gapped. We require the gapped boundary to be stable against quantum fluctuations in order to prevent it from flowing back to the gapless states. Such a gapped boundary must take a stable classical values at the partition function of edge states. From the bosonization techniques, we can map the multi-fermion interactions to the cosine potential term $g_a \cos(\ell_a \cdot \Phi)$. From the bulk-edge correspondence, we learn to regard the 1+1D chiral fermion/boson theory as the edge states of a K matrix Chern-Simons theory, and further learn that the ℓ_a vector is indeed a Wilson line operator of anyons [integer anyons (fermions or bosons) for det(K) = 1 matrix (e.g. SPT states), fractional anyons for det(K) > 1 (e.g. Topological Orders). However, the nontrivial braiding statistics of anyons of ℓ_a vectors will cause quantum fluctuations to the partition function (or the path integral)

$$\mathbf{Z}_{\text{statistics}} \sim \exp[\mathrm{i}\theta_{ab}] = \exp[\mathrm{i}\,2\pi\,\ell_{a,I}K_{IJ}^{-1}\ell_{b,J}]. \tag{45}$$

Here the Abelian braiding statistics angle can be derived from the effective action between anyon vectors ℓ_a, ℓ_b by integrating out the internal gauge field a of the Chern-Simons action $\int \left(\frac{1}{4\pi}K_{IJ}a_I \wedge da_J + a \wedge *j(\ell_a) + a \wedge *j(\ell_b)\right)$. (See Fig.8). In order to define a classically-stable topological gapped boundary, we need to stabilize the unwanted quantum fluctuations. We are forced to choose the trivial statistics for the Wilson lines from the set of interaction terms $g_a \cos(\ell_a \cdot \Phi)$. This requires the trivial statistics rule

Rule (1)
$$\ell_{a,I} K_{IJ}^{-1} \ell_{b,J} = 0,$$
 (46)

known as the Haldane null condition.³⁹

What else rules do we require? For a total N edge modes, $N_L = N_R = N/2$ number of left/right moving free Weyl fermion modes, we need to have at least N/2 interaction terms to open the energy gap. This can be intuitively understood as a pair of modes can be gapped together if it is a pair of one left-moving to one right-moving mode. It turns out that if we include more linear-independent interactions of ℓ_a than N/2 terms, such ℓ_a cannot be compatible with the previous set of N/2 terms for a compatible trivial mutual or self statistics $\theta_{ab} = 0$. So we arrive the Rule (2), "no more or no less than the exact N/2 interaction terms." And implicitly, we must have the Rule (3), " $N_L = N_R = N/2$ number of left/right moving modes."

So from this physical picture, we have the following rules in order to gap out the edge states of Abelian K-matrix Chern-Simons theory:

Boundary Fully Gapping Rules 39,41,42,48,50,52 There exists a Lagrangian $subgroup^{40,42,48}$ $\Gamma^{\partial} \equiv \{\sum_a c_a \ell_{a,I} | c_a \in \mathbb{Z} \}$ (or named as the boundary gapping $lattice^{41}$ in $K_{N\times N}$ Abelian Chern-Simons theory), such that giving a set of interaction terms as the cosine potential terms $g_a \cos(\ell_a \cdot \Phi)$:

(1) $\forall \ell_a, \ell_b \in \Gamma^{\partial}$, the self and mutual statistical angles θ_{ab} are zeros among quasiparticles. Namely,

$$\theta_{ab} \equiv 2\pi \ell_{a,I} K_{IJ}^{-1} \ell_{b,J} = 0. \tag{47}$$

(For a=b, the self-statistical angle $\theta_{aa}/2=0$ is called the self-null condition. And for $a\neq b$, the mutual-statistical angle $\theta_{ab}=0$ is called the mutual-null conditions.³⁹)

- (2) The dimension of the lattice Γ^{∂} is N/2, where N must be an even integer. This means the Chern-Simons lattice Γ^{∂} is spanned by N/2 linear independent vectors of ℓ_a .
- (3) The signature of K matrix (the number of left moving modes the number of left moving modes) is zero. Namely $N_L = N_R = N/2$.
- (4) $\ell_a \in \Gamma_e$, where Γ_e is composed by column vectors of K matrix, namely $\Gamma_e = \{\sum_J c_J K_{IJ} \mid c_J \in \mathbb{Z}\}$. Γ_e is names as the non-fractionalized Chern-Simons lattice. 41,71,79

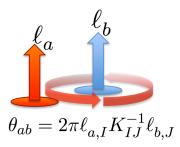

FIG. 8: The braiding statistical angle θ_{ab} of two quasiparticles ℓ_a, ℓ_b , obtained from the phase gain $e^{i\theta_{ab}}$ in the wavefunction by winding ℓ_a around ℓ_b . Here the effective 2+1D Chern-Simons action with the internal 1-form gauge field a_I is $\int \left(\frac{1}{4\pi}K_{IJ}a_I \wedge da_J + a \wedge *j(\ell_a) + a \wedge *j(\ell_b)\right).$ One can integrate out a field to obtain the Hopf term, which coefficient as a self-statistical angle ℓ_a is $\theta_{aa}/2 \equiv \pi \ell_{a,I} K_{IJ}^{-1} \ell_{a,J}$ and the mutual-statistical angle between ℓ_a, ℓ_b is $\theta_{ab} \equiv 2\pi \ell_{a,I} K_{IJ}^{-1} \ell_{b,J}$.

The Rule (4) is an extra rule, which is not of our main concern here. This extra rule is for the ground state degeneracy (GSD) matching between the bulk GSD and the boundary GSD while applying the cutting-glueing(or sewing) relations, studied in Ref.41. (Note that the bulk GSD is the topological ground state degeneracy for a bulk closed manifold without boundary, the boundary GSD is the topological GSD for a compact manifold with gapped boundaries.) Since we have the unimodular indefinite symmetric integral K matrix of Eq.(23),(24), so Rule (4) is always true, for our chiral fermion/boson models.

2. Topological non-perturbative proof

The above physical picture is suggestive, but not yet rigorous enough mathematically. Here we will formulate some topological non-perturbative proofs for **Boundary Fully Gapping Rules**, and its equivalence to the anomaly-matching conditions for the case of U(1) symmetry. The first approach is using the topological quantum field theory(TQFT) along the logic of Ref.40. The new ingredient for us is to find the equivalence of the gapped boundary to the anomaly-matching conditions. We intentionally save the details in Appendix E, especially in E 5.

For a field theory, the boundary condition is defined by a Lagrangian submanifold in the space of Cauchy boundary condition data on the boundary. For a topological gapped boundary condition of a TQFT with a gauge group, we must choose a Lagrangian subspace in the Lie algebra of the gauge group. A subspace is Lagrangian if and only if it is both isotropic and coisotropic.

Specifically, for W be a linear subspace of a finite-dimensional vector space V. Define the symplectic complement of W to be the subspace W^{\perp} as

$$\mathbf{W}^{\perp} = \{ v \in \mathbf{V} \mid \omega(v, w) = 0, \quad \forall w \in \mathbf{W} \}$$
 (48)

Here ω is the symplectic form, in the matrix form $\omega = \begin{pmatrix} 0 & \mathbf{1} \\ -\mathbf{1} & 0 \end{pmatrix}$ with 0 and 1 are the block matrix of the zero and the identity. The symplectic complement \mathbf{W}^{\perp} satisfies: $(\mathbf{W}^{\perp})^{\perp} = \mathbf{W}$, $\dim \mathbf{W} + \dim \mathbf{W}^{\perp} = \dim \mathbf{V}$. We have:

• **W** is Lagrangian if and only if it is both isotropic and coisotropic, namely, if and only if $\mathbf{W} = \mathbf{W}_{\perp}$. In a finite-dimensional \mathbf{V} , a Lagrangian subspace \mathbf{W} is an isotropic one whose dimension is half that of \mathbf{V} .

Now let us focus on the K-matrix $\mathrm{U}(1)^N$ Chern-Simons theory, the symplectic form ω is given by (with the restricted $a_{\parallel,I}$ on $\partial\mathcal{M}$)

$$\omega = \frac{K_{IJ}}{4\pi} \int_{\mathcal{M}} (\delta a_{\parallel,I}) \wedge d(\delta a_{\parallel,J}). \tag{49}$$

The bulk gauge group $\mathrm{U}(1)^N \cong \mathbb{T}_\Lambda$ as the torus, is the quotient space of N-dimensional vector space \mathbf{V} by a subgroup $\Lambda \cong \mathbb{Z}^N$. Locally the gauge field a is a 1-form, which has values in the Lie algebra of \mathbb{T}_Λ , we can denote this Lie algebra \mathbf{t}_Λ as the vector space $\mathbf{t}_\Lambda = \Lambda \otimes \mathbb{R}$.

Importantly, for topological gapped boundary, $a_{\parallel,I}$ lies in a Lagrangian subspace of \mathbf{t}_{Λ} implies that the **boundary gauge group** ($\equiv \mathbb{T}_{\Lambda_0}$) is a **Lagrangian subgroup**. We can rephrase it in terms of the exact sequence for the vector space of Abelian group $\Lambda \cong \mathbb{Z}^N$ and its subgroup Λ_0 :

$$0 \to \Lambda_0 \stackrel{\mathbf{h}}{\to} \Lambda \to \Lambda/\Lambda_0 \to 0. \tag{50}$$

Here 0 means the trivial zero-dimensional vector space and \mathbf{h} is an injective map from Λ_0 to Λ . We can also rephrase it in terms of the exact sequence for the vector space of Lie algebra by $0 \to \mathbf{t}^*_{(\Lambda/\Lambda_0)} \to \mathbf{t}^*_{\Lambda} \to \mathbf{t}^*_{\Lambda_0} \to 0$.

The generic Lagrangian subgroup condition applies to K-matrix with the above symplectic form Eq.(49) renders three conditions on **W**:

- \bullet (i) The subspace **W** is isotropic with respect to the symmetric bilinear form K.
- $\bullet(ii)$ The subspace dimension is a half of the dimension of \mathbf{t}_{Λ} .
- $\bullet(iii)$ The signature of K is zero. This means that K has the same number of positive and negative eigenvalues.

Now we can examine the if and only if conditions $\bullet(i), \bullet(ii), \bullet(iii)$ listed above.

For $\bullet(i)$ "The subspace is isotropic with respect to the symmetric bilinear form K" to be true, we have an extra condition on the injective \mathbf{h} matrix (\mathbf{h} with $N \times (N/2)$ components) for the K matrix:

$$\mathbf{h}^T K \mathbf{h} = 0 \ . \tag{51}$$

Since K is invertible $(\det(K) \neq 0)$, by defining a $N \times (N/2)$ -component $\mathbf{L} \equiv K\mathbf{h}$, we have an equivalent condition:

$$\boxed{\mathbf{L}^T K^{-1} \mathbf{L} = 0}.$$
 (52)

For $\bullet(ii)$, "the subspace dimension is a half of the dimension of \mathbf{t}_{Λ} " is true if Λ_0 is a rank-N/2 integer matrix.

For $\bullet(iii)$, "the signature of K is zero" is true, because our K_{b0} and fermionic K_f matrices implies that we have same number of left moving modes (N/2) and right moving modes (N/2), with $N \in 2\mathbb{Z}^+$ an even number.

Lo and behold, these above conditions $\bullet(i), \bullet(ii), \bullet(iii)$ are equivalent to the **boundary full gapping rules** listed earlier. We can interpret $\bullet(i)$ as trivial statistics by either writing in the column vector of \mathbf{h} matrix $(\mathbf{h} \equiv (\eta_1, \eta_2, \dots, \eta_{N/2})$ with $N \times (N/2)$ -components):

$$\boxed{\eta_{a,I'}K_{I'J'}\eta_{b,J'}=0}. (53)$$

or writing in the column vector of **L** matrix (**L** \equiv $(\ell_1, \ell_2, \dots, \ell_{N/2})$ with $N \times (N/2)$ -components):

$$\boxed{\ell_{a,I} K_{IJ}^{-1} \ell_{b,J} = 0}.$$
(54)

for any $\ell_a, \ell_b \in \Gamma^{\partial} \equiv \{ \sum_{\alpha} c_{\alpha} \ell_{\alpha,I} | c_{\alpha} \in \mathbb{Z} \}$ of boundary gapping lattice(Lagrangian subgroup). Namely,

The boundary gapping lattice Γ^{∂} is basically the N/2dimensional vector space of a Chern-Simons lattice
spanned by the N/2-independent column vectors of \mathbf{L} matrix $(\mathbf{L} \equiv (\ell_1, \ell_2, \dots, \ell_{N/2}))$.

Moreover, we can go a step further to relate the above rules equivalent to the **anomaly-matching conditions**. By adding the corresponding cosine potential $g_a \cos(\ell_a \cdot \Phi)$ to the edge states of $\mathrm{U}(1)^N$ Chern-Simons theory, we break the symmetry down to

$$U(1)^N \to U(1)^{N/2}$$
.

What are the remained $\mathrm{U}(1)^{N/2}$ symmetry? By Eq.(30), this remained $\mathrm{U}(1)^{N/2}$ symmetry is generated by a number of N/2 of $\mathbf{t}_{b,I}$ vectors satisfying $\ell_{a,I} \cdot \mathbf{t}_{b,I} = 0$. We can easily construct

$$\mathbf{t}_{b,I} \equiv K_{II}^{-1} \ell_{b,J}, \quad \mathbf{t} \equiv K^{-1} \mathbf{L}$$
 (55)

with N/2 number of them (or define **t** as the linear-combination of $\mathbf{t}_{b,I} \equiv \sum_{I'} c_{II'}(K_{I'J}^{-1}\ell_{b,J})$). It turns out that $\mathrm{U}(1)^{N/2}$ symmetry is exactly generated by $\mathbf{t}_{b,I}$ with $b=1,\ldots,N/2$, and these remained unbroken symmetry with N/2 of $\mathrm{U}(1)$ generators are **anomaly-free** and **mixed anomaly-free**, due to

$$\mathbf{t}_{a,I'}K_{I'J'}\mathbf{t}_{b,J'} = \ell_{a,I'}K_{I'J'}^{-1}\ell_{b,J'} = 0$$
. (56)

Indeed, \mathbf{t}_a must be anomaly-free, because it is easily notice that by defining an $N \times N/2$ matrix $\mathbf{t} \equiv \left(\mathbf{t}_1, \mathbf{t}_2, \dots, \mathbf{t}_{N/2}\right) = \left(\eta_1, \eta_2, \dots, \eta_{N/2}\right)$ of Eq.(E64), thus we must have:

$$\mathbf{t}^T K \mathbf{t} = 0$$
, where $\mathbf{t} = \mathbf{h}$. (57)

This is exactly the anomaly factor and the effective Hall conductance discussed in Sec.IV B.

In summary of the above, we have provided a topological non-perturbative proof that the Boundary Fully Gapping Rules (following Ref. 40), and its extension to the equivalence relation to the anomaly-matching conditions. We emphasize that Boundary Fully Gapping Rules provide a topological statement on the gapped boundary conditions, which is non-perturbative, while the anomaly-matching conditions are also nonperturbative in the sense that the conditions hold at any energy scale, from low energy IR to high energy UV. Thus, the equivalence between the two is remarkable, especially that both are non-perturbative statements (namely the proof we provide is as exact as integer number values without allowing any small perturbative expansion). Our proof apply to a bulk $U(1)^N$ K matrix Chern-Simons theory (describing bulk Abelian topological orders or Abelian SPT states) with boundary multiplet chiral boson/fermion theories. More discussions can be found in Appendix C, D, E.

3. Perturbative arguments

Apart from the non-perturbative proof using TQFT, we can use other well-known techniques to show the

boundary is gapped when the **Boundary Fully Gapping Rules** are satisfied. Using the techniques systematically studied in Ref.47 and detailed in Appendix E 4, it is convenient to map the $K_{N\times N}$ -matrix multiplet chiral boson theory to N/2 copies of non-chiral Luttinger liquids, each copy with an action

$$\int dt \, dx \, \left(\frac{1}{4\pi} ((\partial_t \bar{\phi}_a \partial_x \bar{\theta}_a + \partial_x \bar{\phi}_a \partial_t \bar{\theta}_a) - V_{IJ} \partial_x \Phi_I \partial_x \Phi_J) + g \cos(\beta \, \bar{\theta}_a) \right)$$
(58)

at large coupling g at the low energy ground state. Notice that the mapping sends $\Phi \to \Phi'' = (\bar{\phi}_1, \bar{\phi}_2, \dots, \bar{\phi}_{N/2}, \bar{\theta}_1, \bar{\theta}_2, \dots, \bar{\theta}_{N/2})$ in a new basis, such that the cosine potential only takes one field $\bar{\theta}_a$ decoupled from the full multiplet. However, this mapping has been shown to be possible $if \mathbf{L}^T K^{-1} \mathbf{L} = 0$ is satisfied.

When the mapping is done (in Appendix E4), we can simply study a single copy of non-chiral Luttinger liquids, and which, by changing of variables, is indeed equivalent to the action of Klein-Gordon fields with a sine-Gordon cosine potential studied by S. Coleman.⁸⁷ We have demonstrated various ways to show the existence of energy gap of this sine-Gordon action in Appendix E3. For example,

- For non-perturbative perspectives, there is a duality between the quantum sine-Gordon action of bosons and the massive Thirring model of fermions in 1+1D. In the sense, it is an integrable model, and the Zamolodchikov formula is known and Bethe ansatz can be applicable. The energy gap is known unambiguously at the large g.
- \bullet For perturbative arguments, we can use $\mathbf{R}\mathbf{G}$ to do weak or strong coupling expansions.

For weak coupling g analysis, it is known that choosing the kinetic term as a marginal term, and the scaling dimension of the normal ordered $[\cos(\beta\bar{\theta})] = \frac{\beta^2}{2}$. In the weak coupling analysis, $\beta^2 < \beta_c^2 \equiv 4$ will flow to the large g gapped phases (with an exponentially decaying correlator) at low energy, while $\beta^2 > \beta_c^2$ will have the low energy flow to the quasi-long-range gapless phases (with an algebraic decaying correlator) at the low energy ground state. At $\beta = \beta_c$, it is known to have Berezinsky-Kosterlitz-Thouless (BKT) transition. We find that our model satisfies $\beta^2 < \beta_c^2$, shown in Appendix F 2 b, thus necessarily flows to gapped phases, because the gapping terms can be written as $g_a \cos(\bar{\theta}_1) + g_b \cos(\bar{\theta}_2)$ in the new basis, where both $\beta^2 = 1 < \beta_c^2$.

However, the weak coupling RG may not account the correct physics at large g.

We also perform the strong coupling g RG analysis, by setting the pin-down fields at large g coupling of $g\cos(\beta\bar{\theta})$ with the quadratic fluctuations as the marginal operators. We find the kinetic term changes to an irrelevant operator. And the two-point correlator at large g coupling exponentially decays implies that our starting point is a strong-coupling fixed point of gapped phase. Such an analysis shows β -independence, where the gapped phase

is universal at strong coupling g regardless the values of β and robust against kinetic perturbation. It implies that there is no instanton connecting different minimum vacua of large-g cosine potential for 1+1D at zero temperature for this particular action Eq.(58). More details in Appendix E 3.

In short, from the mapping to decoupled N/2-copies of non-chiral Luttinger liquids with gapped spectra together with the anomaly-matching conditions proved in Appendix C, D, we obtain the relations:

the U(1)^{N/2} anomaly-free theory
$$(\mathbf{q}^T \cdot K^{-1} \cdot \mathbf{q} = \mathbf{t}^T \cdot K \cdot \mathbf{t} = 0) \text{ with gapping terms } \mathbf{L}^T K^{-1} \mathbf{L} = 0 \text{ satisfied.}$$

the K matrix multiplet-chirla boson theories with gapping terms $\mathbf{L}^T K^{-1} \mathbf{L} = 0$ satisfied.

N/2-decoupled-copies of non-chiral Luttinger liquid actions with gapped energy spectra.

- We can also answer other questions using *perturbative* analysis: (Please see Appendix E 2 for the details of calculation.)
- (Q1) How can we see explicitly the formation of energy gap necessarily requiring trivial braiding statistics among Wilson line operators (the ℓ_a vectors)?
- (A1) To evaluate the mass gap, we need to know the energy gap of the lowest energy state, namely the zero mode. The mode expansion of chiral boson Φ field on a compact circular S^1 boundary of size $0 \le x \le L$ is

$$\Phi_I(x) = \phi_{0I} + K_{IJ}^{-1} P_{\phi_J} \frac{2\pi}{L} x + i \sum_{n \neq 0} \frac{1}{n} \alpha_{I,n} e^{-inx \frac{2\pi}{L}},$$
 (59)

where zero modes ϕ_{0I} and winding modes P_{ϕ_J} satisfy the commutator $[\phi_{0I}, P_{\phi_J}] = \mathrm{i}\delta_{IJ}$; and the Fourier modes satisfy generalized Kac-Moody algebra: $[\alpha_{I,n}, \alpha_{J,m}] = nK_{IJ}^{-1}\delta_{n,-m}$. A perturbative way to figure the zero mode's mass is to learn when the zero mode ϕ_{0I} can be pinned down at the minimum of cosine potential, with only quadratic fluctuations. In that case, we can evaluate the mass by solving the simple harmonic oscillator problem. This requires the following approximation to hold

$$\begin{split} g_a & \int_0^L dx \, \cos(\ell_{a,I} \cdot \Phi_I) \\ & \to g_a \int_0^L dx \, \cos(\ell_{a,I} \cdot (\phi_{0I} + K_{IJ}^{-1} P_{\phi_J} \frac{2\pi}{L} x)) \\ & \to g_a L \, \cos(\ell_{a,I} \cdot \phi_{0I}) \delta_{(\ell_{a,I} \cdot K_{IJ}^{-1} P_{\phi_J}, 0)}. \end{split} \tag{60}$$

In the second line, one neglect the higher energetic Fourier modes; while to have the third line to be true, it demands a commutator, $[\ell_{a,I}\phi_{0I}, \ \ell_{a,I'}K_{I'J}^{-1}P_{\phi_J}] = 0$. Remarkably, this demands the null-condition $\ell_{a,J}K_{I'J}^{-1}\ell_{a,I'} = 0$, and the Kronecker delta function restricts the Hilbert space of winding modes P_{ϕ_J}

residing on the boundary gapping lattice Γ^{∂} due to $\ell_{a,I} \cdot K_{IJ}^{-1} P_{\phi_J} = 0$. Thus, we see that, even at the perturbative level, the formation of energy gap requires trivial braiding statistics among the ℓ_a vectors of interaction terms.

- (Q2) What is the scale of the mass gap?
- (A2) At the *perturbative* level, we compute from a quantum simple harmonic oscillator solution and find the mass gap Δ_m of zero modes:

$$\Delta_m \simeq \sqrt{2\pi \, g_a \ell_{a,l1} \ell_{a,l2} V_{IJ} K_{Il1}^{-1} K_{Jl2}^{-1}},$$

- (Q3) What happens to the mass gap if we include more (incompatible) interaction terms or less interaction terms with respect to the set of interactions dictated by **Boundary Fully Gapping Rules** (adding $\ell' \notin \Gamma^{\partial}$, namely ℓ' is not a linear combination of column vectors of **L**)?
- (A3) Let us check the *stability* of the mass gap against any *incompatible* interaction term ℓ' (which has nontrivial braiding statistics respect to at least one of $\ell_a \in \Gamma^{\partial}$), by adding an extra interaction $g' \cos(\ell_I' \cdot \Phi_I)$ to the original set of interactions $\sum_a g_a \cos(\ell_{a,I} \cdot \Phi_I)$. We find that as $\ell_{a,I} K_{IJ}^{-1} \ell'_J \neq 0$ for the newly added ℓ' , then the energy spectra for zero modes as well as the higher Fourier modes have the *unstable* form:

$$E_n = \left(\sqrt{\Delta_m^2 + \#(\frac{2\pi n}{L})^2 + \sum_a \#g_a \, g'(\frac{L}{n})^2 \dots + \dots} + \dots\right),\tag{61}$$

Here # are denoted as some numerical factors. Comparing to the case for g'=0 (without ℓ' term), the energy changes from the *stable* form $E_n=(\sqrt{\Delta_m^2+\#(\frac{2\pi n}{L})^2}+\dots)$ to the *unstable* form Eq.(61) at long-wave length low energy $(L\to\infty)$, due to the disastrous term $g_a\,g'(\frac{L}{n})^2$. The energy has an infinite jump, either from n=0 (zero mode) to $n\neq 0$ (Fourier modes), or at $L\to\infty$.

With any incompatible interaction term of ℓ' , the preformed mass gap shows an instability. This indicates the perturbative analysis may not hold, and the zero modes cannot be pinned down at the minimum. The consideration of instanton tunneling and talking between different minimum may be important when $\ell_{a,I}K_{IJ}^{-1}\ell_J' \neq 0$. In this case, we expect the massive gapped phase is not stable, and the phase could be gapless. Importantly, this can be one of the reasons why the numerical attempts of Chen-Giedt-Poppitz model finds gapless phases instead of gapped phases. immediate reason is that their Higgs terms induce many extra interaction terms, not compatible with the (trivial braiding statistics) terms dictated by Boundary Fully Gapping Rules. As we checked explicitly, many of their induced terms break the $U(1)_{2nd}$ symmetry 0-4-5-3, which is not compatible to the set inside Γ^{∂} or **L** matrix.

4. Preserved $U(1)^{N/2}$ symmetry and a unique ground state

We would like to discuss the symmetry of the system further. As we mention in Sec.IV C 2, the symmetry is broken down from $\mathrm{U}(1)^N \to \mathrm{U}(1)^{N/2}$ by adding N/2 gapping terms with N=4. In the case of gapping terms $\ell_1=(1,1,-2,2)$ and $\ell_2=(2,-2,1,1)$, we can find the unbroken symmetry by Eq.(55), where the symmetry charge vectors are $\mathbf{t}_1=(1,-1,-2,-2)$ and $\mathbf{t}_2=(2,2,1,-1)$. The symmetry vector can have another familiar linear combination $\mathbf{t}_1=(3,5,4,0)$ and $\mathbf{t}_2=(0,4,5,3)$, which indeed matches to our original $\mathrm{U}(1)_{1\mathrm{st}}$ 3-5-4-0 and $\mathrm{U}(1)_{2\mathrm{nd}}$ 0-4-5-3 symmetries. Similarly, the two gapping terms can have another linear combinations: $\ell_1=(3,-5,4,0)$ and $\ell_2=(0,4,-5,3)$. We can freely choose any linear-independent combination set of the following,

$$\mathbf{L} = \begin{pmatrix} 3 & 0 \\ -5 & 4 \\ 4 & -5 \\ 0 & 3 \end{pmatrix}, \begin{pmatrix} 1 & 2 \\ 1 & -2 \\ -2 & 1 \\ 2 & 1 \end{pmatrix}, \dots$$
 (62)

$$\iff \mathbf{t} = \begin{pmatrix} 3 & 0 \\ 5 & 4 \\ 4 & 5 \\ 0 & 3 \end{pmatrix}, \begin{pmatrix} 1 & 2 \\ -1 & 2 \\ -2 & 1 \\ -2 & -1 \end{pmatrix}, \dots$$

and we emphasize the vector space spanned by the column vectors of \mathbf{L} and \mathbf{t} (the complement space of \mathbf{L} 's) will be the entire 4-dimensional vector space \mathbb{Z}^4 . In Appendix F 2 b, we will provide the lattice construction for the alternative \mathbf{L} , see Eq.(F11).

Now we like to answer:

(Q4) Whether the $\mathrm{U}(1)^{N/2}$ symmetry stays unbroken when the mirror sector becomes gapped by the strong interactions?

(A4) The answer is Yes. We can check: There are two possibilities that $U(1)^{N/2}$ symmetry is broken. One is that it is explicitly broken by the interaction term. This is not true. The second possibility is that the ground state (of our chiral fermions with the gapped mirror sector) spontaneously or explicitly break the $U(1)^{N/2}$ symmetry. This possibility can be checked by calculating its ground state degeneracy(GSD) on the cylinder with gapped boundary. Using the method developing in our previous work Ref.41, also in Ref.46,47, we find GSD=1, there is only a unique ground state. Because there is only one lowest energy state, it cannot spontaneously or explicitly break the remained symmetry. The GSD is 1 as long as the ℓ_a vectors are chosen to be the minimal vector, namely the greatest common divisor(gcd) among each component of any ℓ_a is 1, $|\gcd(\ell_{a,1}, \ell_{a,2}, \dots, \ell_{a,N/2})| = 1$, such that

$$\ell_a \equiv \frac{(\ell_{a,1},\ell_{a,2},\ldots,\ell_{a,N/2})}{|\gcd(\ell_{a,1},\ell_{a,2},\ldots,\ell_{a,N/2})|}.$$

In addition, thanks to Coleman-Mermin-Wagner theorem, there is no spontaneous symmetry breaking for

any continuous symmetry in 1+1D, due to no Goldstone modes in 1+1D, we can safely conclude that $U(1)^{N/2}$ symmetry stays unbroken.

To summarize the whole Sec.IV, we provide both non-perturbative and perturbative analysis on **Boundary Fully Gapping Rules**. This applies to a generic K-matrix $U(1)^N$ Abelian Chern-Simons theory with a boundary multiplet chiral boson theory. (This generic K matrix theory describes general Abelian topological orders including all Abelian SPT states.)

In addition, in the case when K is unimodular indefinite symmetric integral matrix, for both fermions $K = K^f$ and bosons $K = K^{b0}$, we have further proved:

Theorem: The boundary fully gapping rules of 1+1D boundary/2+1D bulk with unbroken $U(1)^{N/2}$ symmetry \leftrightarrow ABJ's $U(1)^{N/2}$ anomaly matching conditions in 1+1D.

Similar to our non-perturbative algebraic result on topological gapped boundaries, the 't Hooft anomaly matching here is a non-perturbative statement, being exact from IR to UV, insensitive to the energy scale.

V. GENERAL CONSTRUCTION OF NON-PERTURBATIVE ANOMALY-FREE CHIRAL MATTER MODEL FROM SPT

As we already had an explicit example of 3_L - 5_R - 4_L - 0_R chiral fermion model introduced in Sec.II,III A 2, and we had paved the way building up tools and notions in Sec.IV, now we are finally here to present our general model construction. Our construction of non-perturbative anomaly-free chiral fermions and bosons model with onsite U(1) symmetry is the following.

Step 1: We start with a K matrix Chern-Simons theory as in Eq.(21),(22) for unimodular indefinite symmetric integral K matrices, both fermions $K = K^f$ of Eq.(23) and bosons $K = K^{b0}$ of Eq.(24) (describing generic Abelian SPT states with GSD on torus is $|\det(K)| = 1$.)

Step 2: We assign charge vectors \mathbf{t}_a of U(1) symmetry as in Eq.(26), which satisfies the anomaly matching condition Eq.(43) for fermionic model, or satisfies Eq.(44) for bosonic model. We can assign up to N/2 charge vector $\mathbf{t} \equiv \left(\mathbf{t}_1, \mathbf{t}_2, \dots, \mathbf{t}_{N/2}\right)$ with a total U(1) $^{N/2}$ symmetry with the matching $\mathcal{A} = \mathbf{t}^T K \mathbf{t} = 0$ such that the model is anomaly and mixed-anomaly free.

Step 3: In order to be a *chiral* theory, it needs to *violate the parity symmetry*. In our model construction, assigning $q_{L,j} \neq q_{R,j}$ generally fulfills our aims by breaking both parity and time reversal symmetry. (See Appendix A for details.)

Step 4: By the equivalence of the anomaly matching condition and boundary fully gapping rules(proved in Sec.IV C 2 and Appendix C,D), our anomaly-free theory guarantees that a proper choice of gapping terms of Eq.(29) can fully gap out the edge states. For $N_L = N_R = N/2$ left/right Weyl fermions, there are N/2 gapping terms ($\mathbf{L} \equiv \left(\ell_1, \ell_2, \dots, \ell_{N/2}\right)$), and the U(1) symmetry can be extended to U(1)^{N/2} symmetry by finding the corresponding N/2 charge vectors ($\mathbf{t} \equiv \left(\mathbf{t}_1, \mathbf{t}_2, \dots, \mathbf{t}_{N/2}\right)$). The topological non-perturbative proof found in Sec.IV C 2 guarantees the duality relation:

$$\left| \mathbf{L}^T \cdot K^{-1} \cdot \mathbf{L} = 0 \stackrel{\mathbf{t} = K^{-1} \mathbf{L}}{\longleftrightarrow} \mathbf{t}^T \cdot K \cdot \mathbf{t} = 0 \right|. \quad (63)$$

Given K as a $N \times N$ -component matrix of K^f or K^{b0} , we have **L** and **t** are both $N \times (N/2)$ -component matrices.

So our strategy is that constructing the bulk SPT on a 2D spatial lattice with two edges (for example, a cylinder in Fig.2,Fig.7). The low energy edge property of the 2D lattice model has the same continuum field theory⁶⁹ as we had in Eq.(22), and selectively only fully gapping out states on one mirrored edge with a large energy gap by adding symmetry allowed gapping terms Eq.(29), while leaving the other side gapless edge states untouched.²⁸

In summary, we start with a chiral edge theory of SPT states with $\cos(\ell_I \cdot \Phi_I^B)$ gapping terms on the edge B, which action is

$$S_{\Phi} = \frac{1}{4\pi} \int dt dx \left(K_{IJ}^{A} \partial_{t} \Phi_{I}^{A} \partial_{x} \Phi_{J}^{A} - V_{IJ} \partial_{x} \Phi_{I}^{A} \partial_{x} \Phi_{J}^{A} \right)$$

$$+ \frac{1}{4\pi} \int dt dx \left(K_{IJ}^{B} \partial_{t} \Phi_{I}^{B} \partial_{x} \Phi_{J}^{B} - V_{IJ} \partial_{x} \Phi_{I}^{B} \partial_{x} \Phi_{J}^{B} \right)$$

$$+ \int dt dx \sum_{a} g_{a} \cos(\ell_{a,I} \cdot \Phi_{I}).$$

$$(64)$$

We fermionize the action to:

$$S_{\Psi} = \int dt \, dx \, (i\bar{\Psi}_{A}\Gamma^{\mu}\partial_{\mu}\Psi_{A} + i\bar{\Psi}_{B}\Gamma^{\mu}\partial_{\mu}\Psi_{B} + U_{\text{interaction}}(\tilde{\psi}_{q}, \dots, \nabla_{x}^{n}\tilde{\psi}_{q}, \dots)).$$
(65)

with Γ^0 , Γ^1 , Γ^5 follow the notations of Eq.(25).

The gapping terms on the field theory side need to be irrelevant operators or marginally irrelevant operators with appropriate strength (to be order 1 intermediate-strength for the dimensionless lattice coupling $|G|/|t_{ij}| \gtrsim O(1)$), so it can gap the mirror sector, but it is weak enough to keep the original light sector gapless.

Use several copies of Chern bands to simulate the free kinetic part of Weyl fermions, and convert the higher-derivatives fermion interactions $U_{\rm interaction}$ to the point-splitting $U_{\rm point.split.}$ term on the lattice, we propose its

corresponding lattice Hamiltonian

$$H = \sum_{q} \left(\sum_{\langle i,j \rangle} \left(t_{ij,q} \, \hat{f}_{q}^{\dagger}(i) \hat{f}_{q}(j) + h.c. \right) \right)$$

$$+ \sum_{\langle \langle i,j \rangle \rangle} \left(t'_{ij,q} \, \hat{f}_{q}^{\dagger}(i) \hat{f}_{q}(j) + h.c. \right)$$

$$+ \sum_{j \in \mathcal{B}} U_{\text{point.split.}} \left(\hat{f}_{q}(j), \dots \left(\hat{f}_{q}^{n}(j) \right)_{pt.s.}, \dots \right).$$

$$(66)$$

Our key to avoid Nielsen-Ninomiya challenge $^{6-8}$ is that our model has the *properly-desgined* interactions.

We have obtained a 1+1D non-perturbative lattice Hamiltonian construction (and realization) of anomaly-free massless chiral fermions (and chiral bosons) on one gapless edge.

For readers with interests, In Appendix F 2, we will demonstrate a step-by-step construction on several lattice Hamiltonian models of chiral fermions(such as 1_L -(1_R) chiral fermion model and 3_L - 5_R - 4_L - 0_R chiral fermion model) and chiral bosons, based on our general prescription above. In short, such our approach is generic for constructing many lattice chiral matter models in 1+1D.

VI. CONCLUSION

We have proposed a 1+1D lattice Hamiltonian definition of non-perturbative anomaly-free chiral matter models with U(1) symmetry. Our 3_L - 5_R - 4_L - 0_R fermion model is under the framework of the mirror fermion decoupling approach. However, some importance essences make our model distinct from the lattice models of Eichten-Preskill¹⁷ and Chen-Giedt-Poppitz 3-4-5 model.²⁵ The differences between our and theirs are:

Onsite or non-onsite symmetry. Our model only implements onsite symmetry, which can be easily to be gauged. While Chen-Giedt-Poppitz model implements Ginsparg-Wilson(GW) fermion approach with non-onsite symmetry(details explained in Appendix B). To have GW relation $\{D, \gamma^5\} = 2aD\gamma^5D$ to be true (a is the lattice constant), the Dirac operator is non-onsite (not strictly local) as $D(x_1, x_2) \sim e^{-|x_1 - x_2|/\xi}$ but with a distribution range ξ . The axial U(1)_A symmetry is modified

$$\delta\psi(y) = \sum_{w} i \,\theta_A \hat{\gamma}_5(y, w) \psi(w), \quad \delta\bar{\psi}(x) = i \,\theta_A \bar{\psi}(x) \gamma_5$$

with the operator $\hat{\gamma}_5(x,y) \equiv \gamma_5 - 2a\gamma_5 D(x,y)$. Since its axial U(1)_A symmetry transformation contains D and the Dirac operator D is non-onsite, the GW approach necessarily implements non-onsite symmetry. GW fermion has non-onsite symmetry in the way that it cannot be written as the tensor product structure on each site: $U(\theta_A)_{\text{non-onsite}} \neq \bigotimes_j U_j(\theta_A)$, for $e^{i\theta_A} \in U(1)_A$.

The Neuberger-Dirac operator also contains such a non-onsite symmetry feature. The non-onsite symmetry is the signature property of the boundary theory of SPT states. The non-onsite symmetry causes GW fermion diffcult to be gauged to a chiral gauge theory, because the gauge theory is originally defined by gauging the local (on-site) degrees of freedom.

Interaction terms. Our model has properly chosen a particular set of interactions satisfying the Eq.(63), from the Lagrangian subgroup algebra to define a topological gapped boundary conditions. On the other hand, Chen-Giedt-Poppitz model proposed different kinds of interactions - all Higgs terms obeying $U(1)_{1st}$ 3-5-4-0 symmetry (Eq.(2.4) of Ref.25), including the Yukawa-Dirac term:

$$\int dt dx \Big(g_{30} \psi_{L,3}^{\dagger} \psi_{R,0} \phi_h^{-3} + g_{40} \psi_{L,4}^{\dagger} \psi_{R,0} \phi_h^{-4} + g_{35} \psi_{L,3}^{\dagger} \psi_{R,5} \phi_h^2 + g_{45} \psi_{L,4}^{\dagger} \psi_{R,5} \phi_h^1 + h.c. \Big), \quad (67)$$

with Higgs field $\phi_h(x,t)$ carrying charge (-1). There are also Yukawa-Majorana term:

$$\int dt dx \Big(ig_{30}^{M} \psi_{L,3} \psi_{R,0} \phi_{h}^{3} + ig_{40}^{M} \psi_{L,4} \psi_{R,0} \phi_{h}^{4} + ig_{35}^{M} \psi_{L,3} \psi_{R,5} \phi_{h}^{8} + ig_{45}^{M} \psi_{L,4} \psi_{R,5} \phi_{h}^{9} + h.c. \Big), (68)$$

Notice that the Yukawa-Majorana coupling has an extra imaginary number i in the front, and implicitly there is also a Pauli matrix σ_y if we write the Yukawa-Majorana term in the two-component Weyl basis.

The question is: How can we compare between interactions of ours and Ref.25's? If integrating out the Higgs field ϕ_h , we find that:

- (*1) Yukawa-Dirac terms of Eq.(67) cannot generate any of our multi-fermion interactions of **L** in Eq.(62) for our 3_L - 5_R - 4_L - 0_R model.
- (*2) Yukawa-Majorana terms of Eq.(68) cannot generate any of our multi-fermion interactions of $\bf L$ in Eq.(62) for our 3_L - 5_R - 4_L - 0_R model.
- (*3) Combine Yukawa-Dirac and Yukawa-Majorana terms of Eq.(67),(68), one can indeed generate the multi-fermion interactions of L in Eq. (62); however, many more multi-fermion interactions outside of the Lagrangian subgroup (not being spanned by L) are generated. Those extra unwanted multi-fermion interactions do not obey the boundary fully gapping rules. As we have shown in Sec. IV C 3 and Appendix E 2, those extra unwanted interactions induced by the Yukawa term will cause the pre-formed mass gap unstable due to the nontrivial braiding statistics between the interaction This explains why the massless mirror sector is observed in Ref.25. In short, we know that Ref.25's interaction terms are different from us, and know that the properly-designed interactions are crucial, and our proposal will succeed the mirror-sector-decoupling even if Ref. 25 fails.

 $\mathbf{U}(1)^N \to \mathbf{U}(1)^{N/2} \to \mathbf{U}(1)$. We have shown that for a $\overline{\text{given } N_L = N_R = N/2 \text{ equal-number-left-right moving}}$ mode theory, the N/2 gapping terms break the symmetry from $\mathrm{U}(1)^N \to \mathrm{U}(1)^{N/2}$. Its remained $\mathrm{U}(1)^{N/2}$ symmetry is unbroken and mixed-anomaly free. Is it possible to further add interactions to break $U(1)^{N/2}$ to a smaller symmetry, such as a single U(1)? For example, breaking the $U(1)_{2nd}$ 0-4-5-3 of 3_L - 5_R - 4_L - 0_R model to only a single U(1)_{1st} 3-5-4-0 symmetry remained. We argue that it is doable. Adding any extra explicit-symmetry-breaking term may be incompatible to the original Lagrangian subgroup and thus potentially ruins the stability of the energy gap. Nonetheless, as long as we add an extra interaction term(breaking the $U(1)_{2nd}$ symmetry), which is irrelevant operator with a tiny coupling, it can be weak enough not driving the system to gapless states. Thus, our setting to obtain 3-5-4-0 symmetry is still quite different from Chen-Giedt-Poppitz where the universal strong couplings are applied.

We show that GW fermion approach implements the non-onsite symmetry (more in Appendix B), thus GW can avoid the fermion-doubling no-go theorem (limited to an onsite symmetry) to obtain chiral fermion states. This realization is consistent with what had been studied in Ref. 29,30,38. Remarkably, this also suggests that

The nontrivial edge states of SPT order,²⁹ such as topological insulators^{82–84} alike, can be obtained in its own dimension (without the need of an extra dimension to the bulk) by implementing the *non-onsite symmetry* as Ginsparg-Wilson fermion approach.

To summarize, so far we have realized (see Fig.9),

- Nielsen-Ninomiya theorem claims that local free chiral fermions on the lattice with onsite (U(1) or chiral³¹) symmetry have fermion-doubling problem in even dimensional spacetime.
- Gilzparg-Wilson(G-W) fermions: quasi-local free chiral fermions on the lattice with non-onsite U(1) symmetry³¹ have no fermion doublers. G-W fermions correspond to gapless edge states of a non-trivial SPT state.
- Our 3-5-4-0 chiral fermion and general model constructions: local interacting chiral fermions on the lattice with onsite U(1) symmetry³¹ have no fermion-doublers. Our model corresponds to unprotected gapless edge states of a trivial SPT state (i.e. a trivial insulator).

We should also clarify that, from SPT classification viewpoint, all our chiral fermion models are in the same class of $K^f = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ with $\mathbf{t} = (1, -1)$, a trivial class in the fermionic SPT with U(1) symmetry. 50,73,81 All our chiral boson models are in the same class of $K^b = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ with $\mathbf{t} = (1,0)$, a trivial class in the bosonic SPT with U(1) symmetry. 50,73,81 In short, we understand that

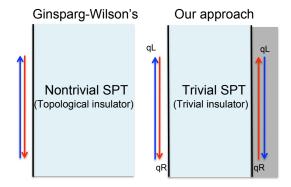

FIG. 9: Gilzparg-Wilson fermions can be viewed as putting gapless states on the edge of a nontrivial SPT state (e.g. topological insulator). Our approach can be viewed as putting gapless states on the edge of a trivial SPT state (trivial insulator).

From the 2+1D bulk theory viewpoint, all our chiral matter models are *equivalent* to the *trivial class* of SPT(trivial bulk insulator) in SPT classification. However, the 1+1D boundary theories with different U(1) charge vectors \mathbf{t} can be regarded as *different* chiral matter theories on its own 1+1D.

Proof of a Special Case and some Conjectures

At this stage we already fulfill proposing our models, on the other hand the outcome of our proposal becomes fruitful with deeper implications. We prove that, at least for 1+1D boundary/2+1D bulk SPT states with U(1) symmetry,

There are equivalence relations between

- (a) "'t Hooft anomaly matching conditions satisfied",
- (b) "the boundary fully gapping rules satisfied",
- (c) "the effective Hall conductance is zero," and
- (d) "a bulk trivial SPT (i.e. trivial insulator), with unprotected boundary edge states (realizing an onsite symmetry) which can be decoupled from the bulk."

Rigorously speaking, what we actually prove in Sec.IV C 2 and Appendix C,D is the equivalence of

Theorem: ABJ's U(1) anomaly matching condition in 1+1D \leftrightarrow the boundary fully gapping rules of 1+1D boundary/2+1D bulk with unbroken U(1) symmetry for an equal number of left-right moving Weyl-fermion modes($N_L = N_R$, $c_L = c_R$) of 1+1D theory.

Note that some modifications are needed for more generic cases:

- (i) For unbalanced left-right moving modes, the number chirality also implies the additional gravitational anomaly.
- (ii) For a bulk with topological order (instead of pure SPT states), even if the boundary is gappable without breaking the symmetry, there still can be nontrivial signature on the boundary, such as degenerate ground states (with

gapped boundaries) or surface topological order. This modifies the above specific Theorem to a more general Conjecture:

Conjecture: The anomaly matching condition in $(d+1)D \leftrightarrow$ the boundary fully gapping rules of (d+1)D boundary/(d+2)D bulk with unbroken G symmetry for an equal number of left-right moving modes($N_L = N_R$) of (d+1)D theory, such that the system with arbitrary gapped boundaries has a unique non-degenerate ground state(GSD=1), 41,46 no surface topological order, 85 no symmetry/quantum number fractionalization 86 and without any nontrivial(anomalous) boundary signature.

However, for an arbitrary given theory, we do not know "all kinds of anomalies," and thus in principle we do not know "all anomaly matching conditions." However, our work reveals some deep connection between the "anomaly matching conditions" and the "boundary fully gapping rules." Alternatively, if we take the following statement as a definition instead,

Proposed Definition: The anomaly matching conditions (all anomalies need to be cancelled) for symmetry $G \leftrightarrow$ the boundary fully gapping rules without breaking symmetry G and without anomalous boundary signatures under gapped boundary.

then the Theorem and the Proposed Definition together reveal that

The only anomaly type of a theory with an equal number of left/right-hand Weyl fermion modes and only with a U(1) symmetry in 1+1D is ABJ's U(1) anomaly.

Arguably the most interesting future direction is to test our above conjecture for more general cases, such as other dimensions or other symmetry groups. One may test the above statements via the modular invariance^{42,80} of boundary theory. It will also be profound to address, the boundary fully gapping rules for non-Abelian symmetry, and the anomaly matching condition for non-ABJ anomaly^{27,28,62,88} through our proposal.

Though being numerically challenging, it will be interesting to test our models on the lattice. Our local spatial-lattice Hamiltonian with a finite Hilbert space, onsite symmetry and short-ranged hopping/interaction terms is exactly a condensed matter system we can realize in the lab. It may be possible in the future we can simulate the lattice chiral model in the physical instant time using the condensed matter set-up in the lab (such as in cold atoms system). Such a real-quantum-world simulation may be much faster than any classical computer or quantum computer.

Acknowledgments

We are grateful to Erich Poppitz, John Preskill, and Edward Witten for very helpful feedback and generous comments on our work. We thank Michael Levin for important conversations at the initial stage and for his comments on the manuscript. JW also thanks Jordan Cotler for very helpful feedbacks and for his interests. JW thanks Roman Jackiw, Anton Kapustin, Thierry Giamarchi, Alexander Altland, Sung-Sik Lee, Yanwen Shang, Duncan Haldane, Shinsei Ryu, David Senechal, Eduardo Fradkin, Subir Sachdev, Ting-Wai Chiu, Jiunn-Wei Chen, Chenjie Wang, and Luiz Santos for comments. JW thanks H. He, L. Cincio, R. Melko and G. Vidal for comments on DMRG.

Appendix

In the Appendix A, we discuss the C, P, T symmetry in an 1+1 D fermion theory. In the Appendix B, we show that Ginsparg-Wilson fermions realizing its axial U(1) symmetry by a non-onsite symmetry transformation. In the Appendix C and D, under the specific assumption for a 2+1D bulk Abelian symmetric protected topological (SPT) states $^{27-29}$ with U(1) symmetry, we prove that

Boundary fully gapping rules (in Sec.IV C) 39,41,42,48,50 are sufficient and necessary conditions of the 't Hooft anomaly matching condition (in Sec.IV B). 58

The SPT order (explained in Sec.IV A) are short-range entangled states with some onsite symmetry G in the bulk. For the nontrivial SPT order, the symmetry G is realized as a non-onsite symmetry on the boundary. 29,37,38 The 1+1D edge states are protected to be gapless as long as the symmetry G is unbroken on the boundary. 29,50 Importantly, SPT has no long-range entanglement, so no gravitational anomalies. 27,28 The only anomaly here is the ABJ's U(1) anomaly 5,74,75 for chiral matters.

Appendix E includes several approaches for proving boundary fully gapping rules. In the Appendix F, we discuss the property of our Chern insulator in details, and provide additional models of lattice chiral fermions and chiral bosons.

Appendix A: C, P, T symmetry in the 1+1D fermion theory

Here we show the charge conjugate C, parity P, time reversal T symmetry transformation for the 1+1D Dirac fermion theory. Recall that the massless Dirac fermion Lagrangian is $\mathcal{L} = \bar{\Psi}i\gamma^{\mu}\partial_{\mu}\Psi$. Here the Dirac fermion field Ψ can be written as a two-component spinor. For

convenience, but without losing the generality, we choose the Weyl basis, so $\Psi = (\psi_L, \psi_R)$, where each component of ψ_L, ψ_R is a chiral Weyl fermion with left and right chirality respectively. Specifically, gamma matrices in the Weyl basis are

$$\gamma^0 = \sigma_x, \quad \gamma^1 = i\sigma_y, \quad \gamma^5 = \gamma^0 \gamma^1 = -\sigma_z.$$
 (A1)

satisfies Clifford algebra $\{\gamma^{\mu},\gamma^{\nu}\}=2\eta^{\mu\nu}$, here the signature of the Minkowski metric is (+,-). The projection operators are

$$P_L = \frac{1 - \gamma^5}{2} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \ P_R = \frac{1 + \gamma^5}{2} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad (A2)$$

mapping a massless Dirac fermion to two Weyl fermions, i.e. $\mathcal{L}=i\psi_L^\dagger(\partial_t-\partial_x)\psi_L+i\psi_R^\dagger(\partial_t+\partial_x)\psi_R$. We derive the P,T,C transformation on the fermion field operator $\hat{\Psi}$ in $1+1\mathrm{D}$, up to some overall complex phases η_P,η_T degree of freedom,

$$P\hat{\Psi}(t,\vec{x})P^{-1} = \eta_P \gamma^0 \hat{\Psi}(t, -\vec{x}), \tag{A3}$$

$$T\hat{\Psi}(t,\vec{x})T^{-1} = \eta_T \gamma^0 \hat{\Psi}(-t,\vec{x}),$$
 (A4)

$$C\hat{\Psi}(t,\vec{x})C^{-1} = \gamma^0 \gamma^1 \hat{\Psi}^*(t,\vec{x}).$$
 (A5)

We can quickly verify these transformations (which works for a massive Dirac fermion): For the P transformation, $P(t,\vec{x})P^{-1}=(t,-\vec{x})\equiv x'^{\mu}$. Multiply Dirac equation by γ^0 , one obtain $\gamma^0(i\gamma^{\mu}\partial_{\mu}+m)\Psi(t,\vec{x})=(i\gamma^{\mu}\partial'_{\mu}+m)(\gamma^0\Psi(t,\vec{x}))=0$. This means we should identify $\Psi'(t,-\vec{x})=\gamma^0\Psi(t,\vec{x})$ up to a phase in the state vector (wavefunction) form. Thus, in the operator form, we derive $P\hat{\Psi}(t,\vec{x})P^{-1}=\hat{\Psi}'(t,\vec{x})=\eta_P\gamma^0\hat{\Psi}(t,-\vec{x})$.

For the T transformation, one massages the Dirac equation in terms of Schrödinger equation form, $i\partial_t \Psi(t,\vec{x}) = H\Psi(t,\vec{x}) = (-i\gamma^0\gamma^j\partial_j + m)\Psi(t,\vec{x})$, here $\Psi(t,\vec{x})$ in the state vector form. In the time reversal form: $i\partial_{-t}\Psi'(-t,\vec{x}) = H\Psi'(-t,\vec{x})$, this is $i\partial_{-t}T\Psi(t,\vec{x}) = HT\Psi(t,\vec{x})$. We have $T^{-1}HT = H$ and $T^{-1}i\partial_{-t}T = i\partial_t$,

where T is anti-unitary. T can be written as T=UK with a unitary transformation part U and an extra K does the complex conjugate. Then $T^{-1}HT=H$ imposes the constraints $U^{-1}\gamma^0U=\gamma^{0*}$ and $U^{-1}\gamma^jU=-\gamma^{j*}$. In 1+1D Weyl basis, since γ^0, γ^1 both are reals, we conclude that $U=\gamma^0$ up to a complex phase. So in the operator form, $T\hat{\Psi}(t,\vec{x})T^{-1}=\hat{\Psi}'(t,\vec{x})=\eta_T\gamma^0\hat{\Psi}(-t,\vec{x})$

For the C transformation, we transform a particle to its anti-particle. This means that we flip the charge q (in the term coupled to a gauge field A), which can be done by taking the complex conjugate on the Dirac equation, $\left[-i\gamma^{\mu*}(\partial_{\mu}+iqA_{\mu})+m\right]\Psi^{*}(t,\vec{x})=0$, where $-\gamma^{\mu*}$ satisfies Clifford algebra. We can rewrite the equation as $\left[i\gamma^{\mu}(\partial_{\mu}+iqA_{\mu})+m\right]\Psi_{c}(t,\vec{x})=0$, by identifying the charge conjugate state vector as $\Psi_{c}=M\gamma^{0}\Psi^{*}$ and imposing the constraint $-M\gamma^{0}\gamma^{\mu*}\gamma^{0}M^{-1}=\gamma^{\mu}$. Additionally, we already have $\gamma^{0}\gamma^{\mu}\gamma^{0}=\gamma^{\mu\dagger}$. So the constraint reduces to $-M\gamma^{\mu T}M^{-1}=\gamma^{\mu}$. In the 1+1D Weyl basis, we obtain $-M\gamma^{0}M^{-1}=\gamma^{0}$ and $M\gamma^{1}M^{-1}=\gamma^{1}$. Thus, $M=\eta_{C}\gamma^{1}$ up to a phase, and we derive $\Psi_{c}=\gamma^{0}\gamma^{1}\Psi^{*}$ in the state vector. In the operator form, we obtain $C\hat{\Psi}(t,\vec{x})C^{-1}=\hat{\Psi}_{c}(t,\vec{x})=\gamma^{0}\gamma^{1}\hat{\Psi}^{*}(t,\vec{x})$.

The important feature is that our chiral matter theory has parity P and time reversal T symmetry broken. Because the symmetry transformation acting on the state vector induces $P\Psi = \sigma_x \Psi = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \Psi$ and $T\Psi = i\sigma_y K\Psi = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} K\Psi$. So both P and T exchange left-handness, right-handness particles, i.e. ψ_L, ψ_R becomes ψ_R, ψ_L . Thus P, T transformation switches left, right charge by switching its charge carrier. If $q_L \neq q_R$, then our chiral matter theory breaks P and T.

Our chiral matter theory, however, does not break charge conjugate symmetry C. Because the symmetry transformation acting on the state vector induces $C\Psi = -\sigma_z \Psi^* = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} \Psi^*$, while ψ_L, ψ_R maintains its left-handness, right-handness as ψ_L, ψ_R .

Appendix B: Ginsparg-Wilson fermions with a non-onsite U(1) symmetry as SPT edge states

We firstly review the meaning of onsite symmetry and non-onsite symmetry transformation, 29,30 and then we will demonstrate that Ginsparg-Wilson fermions realize the U(1) symmetry in the non-onsite symmetry manner.

1. On-site symmetry and non-onsite symmetry

The onsite symmetry transformation as an operator U(g), with $g \in G$ of the symmetry group, transforms the state $|v\rangle$ globally, by $U(g)|v\rangle$. The onsite symmetry transformation U(g) must be written in the tensor product form acting on each site i, 29,30

$$U(g) = \bigotimes_i U_i(g), \quad g \in G.$$
 (B1)

For example, consider a system with only two sites. Each site with a qubit degree of freedom (i.e. with |0|)

and $|1\rangle$ eigenstates on each site). The state vector $|v\rangle$ for the two-sites system is $|v\rangle = \sum_{j_1,j_2} c_{j_1,j_2} |j_1\rangle \otimes |j_2\rangle = \sum_{j_1,j_2} c_{j_1,j_2} |j_1,j_2\rangle$ with 1,2 site indices and $|j_1\rangle, |j_2\rangle$ are eigenstates chosen among $|0\rangle, |1\rangle$.

An example for the onsite symmetry transformation can be,

$$U_{\text{onsite}} = |00\rangle\langle00| + |01\rangle\langle01| - |10\rangle\langle10| - |11\rangle\langle11|$$

= $(|0\rangle\langle0| - |1\rangle\langle1|)_1 \otimes (|0\rangle\langle0| + |1\rangle\langle1|)_2$
= $\otimes_i U_i(g)$. (B2)

Here U_{onsite} is in the tensor product form, where $U_1(g) = (|0\rangle\langle 0| - |1\rangle\langle 1|)_1$ and $U_2(g) = (|0\rangle\langle 0| + |1\rangle\langle 1|)_2$, again with 1,2 subindices are site indices. Importantly, this operator does not contain non-local information between the neighbored sites.

A non-onsite symmetry transformation $U(g)_{\text{non-onsite}}$ cannot be expressed as a tensor product form:

$$U(g)_{\text{non-onsite}} \neq \bigotimes_i U_i(g), \quad g \in G.$$
 (B3)

An example for the non-onsite symmetry transformation can be the CZ operator, ³⁰

$$CZ = |00\rangle\langle 00| + |01\rangle\langle 01| + |10\rangle\langle 10| - |11\rangle\langle 11|.$$

CZ operator contains non-local information between the neighbored sites, which flips the sign of the state vector if both sites 1,2 are in the eigenstate $|1\rangle$. One cannot achieve writing CZ as a tensor product structure.

Now let us discuss how to gauge the symmetry. Gauging an onsite symmetry simply requires replacing the group element g in the symmetry group to g_i with a site dependence, i.e. replacing a global symmetry to a local (gauge) symmetry. All we need to do is,

$$U(g) = \bigotimes_i U_i(g) \stackrel{Gauge}{\Longrightarrow} U(g_i) = \bigotimes_i U_i(g_i),$$
 (B4)

with $g_i \in G$. Following Eq.(B4), it is easy to gauge such an onsite symmetry to obtain a chiral fermion theory coupled to a gauge field. Since our chiral matter theory is implemented with an onsite U(1) symmetry, it is easy to gauge our chiral matter theory to be a U(1) chiral gauge theory.

On the other hand, a non-onsite symmetry transformation cannot be written as a tensor product form. So, it is difficult (or unconventional) to gauge a non-onsite symmetry. As we will show below Ginsparg-Wilson fermions realizing a non-onsite symmetry, so that is why it is difficult to gauge it.

2. Ginsparg-Wilson relation, Wilson fermions and non-onsite symmetry

Below we attempt to show that Wilson fermions implemented with Ginsparg-Wilson (G-W) relation realizing the symmetry transformation by the non-onsite manner. Follow the notation of Ref.57, the generic form of the

Dirac fermion Ψ path integral on the lattice (with the lattice constant a) is

$$\int \mathcal{D}\bar{\Psi}\mathcal{D}\Psi \exp[a^{\mathbf{d}_m} \sum_{x_1, x_2} \bar{\Psi}(x_1)D(x_1, x_2)\Psi(x_2)]. \quad (B5)$$

Here the exponent d_m is the dimension of the spacetime. For example, the action of Wilson fermions with Wilson

term (the term with the front coefficient r) can be written as:

$$S_{\Psi} = a^{\mathrm{d}_{m}} \Big(\sum_{x,\mu} \frac{\mathrm{i}}{2a} (\bar{\psi}(x)\gamma^{\mu}U_{\mu}(x)\psi(x+a^{\mu}) - \bar{\psi}(x+a^{\mu})\gamma^{\mu}U_{\mu}^{\dagger}(x)\psi(x)) - m_{0}\bar{\psi}(x)\psi(x) + \frac{r}{2a} \sum_{x,\mu} \bar{\psi}(x)U_{\mu}(x)\psi(x+a^{\mu}) + \bar{\psi}(x+a^{\mu})U_{\mu}^{\dagger}(x)\psi(x) - 2\bar{\psi}(x)\psi(x) \Big).$$
 (B6)

Here $U_{\mu}(x) \equiv \exp(iagA_{\mu})$ are the gauge field connection. At the weak g coupling, it is also fine for us simply consider $U_{\mu}(x) \simeq 1$. One can find its Fermion propagator:

$$\left(\sum_{\mu} \frac{1}{a} \gamma^{\mu} \sin(ak_{\mu}) - m_0 - \sum_{\mu} \frac{r}{a} (1 - \cos(ak_{\mu}))\right)^{-1}.$$

The Wilson fermions with $r \neq 0$ kills the doubler (at $k_{\mu} = \pi/a$) by giving a mass of order r/a to it. As $a \to 0$, the doubler disappears from the spectrum with an infinite

This Dirac operator $D(x_1, x_2)$ is not strictly local, but decreases exponentially as

$$D(x_1, x_2) \sim e^{-|x_1 - x_2|/\xi}$$
 (B7)

with $\xi = (\text{local range}) \cdot a$ as some localized length scale of the Dirac operator. We call $D(x_1, x_2)$ as a quasi-local operator, which is strictly non-local.

One successful way to treat the lattice Dirac operator is imposing the Ginsparg-Wilson (G-W) relation:³²

$$\{D, \gamma^5\} = 2aD\gamma^5D. \tag{B8}$$

Thus in the continuum limit $a \to 0$, this relation becomes $\{\mathcal{D}, \gamma^5\} = 0$. One can choose a Hermitian γ^5 , and ask for the Hermitian property on $\gamma^5 D$, which is $(\gamma^5 D)^{\dagger} =$ $D^{\dagger} \gamma^5 = \gamma^5 D.$

It can be shown that the action (in the exponent of the path integral) is invariant under the axial U(1) chiral transformation with a θ_A rotation:

$$\delta\psi(y) = \sum_{w} i\theta_{A}\hat{\gamma}^{5}(y, w)\psi(w), \quad \delta\bar{\psi}(x) = i\theta_{A}\bar{\psi}(x)\gamma^{5}$$
(B9)

where

$$\hat{\gamma}^5(x,y) \equiv \gamma^5 - 2a\gamma^5 D(x,y). \tag{B10}$$

The chiral anomaly on the lattice can be reproduced from the Jacobian J of the path integral measure:

$$J = \exp[-i\theta_A \operatorname{tr}(\hat{\gamma}^5 + \gamma^5)] = \exp[-2i\theta_A \operatorname{tr}(\Gamma^5)] \quad (B11)$$

here $\Gamma^5(x,y) \equiv \gamma^5 - a\gamma^5 D(x,y)$. The chiral anomaly follows the index theorem $\operatorname{tr}(\Gamma^5) = n_+ - n_-$, with n_{\pm} counts the number of zero mode eigenstates ψ_j , with zero eigenvalues, i.e. $\gamma^5 D\psi_j = 0$, where the projection is $\gamma^5 \psi_j = \pm \psi_j$ for n_\pm respectively. Note that G-W relation can be rewritten as

$$\gamma^5 D + D\hat{\gamma}^5 = 0. \tag{B12}$$

Importantly, now axial U(1)_A transformation in Eq.(B9) involves with $\hat{\gamma}_5(x,y)$ which contains the piece of quasi-local operators $D(x,y) \sim e^{-|x_1-x_2|/\xi}$. Thus, it becomes apparent that $U(1)_A$ transformation Eq.(B9) is an non-onsite symmetry which carries nonlocal information between different sites x_1 and x_2 . It is analogous to the CZ symmetry transformation in Eq.(B4), which contains the entangled information between neighbored sites j_1 and j_2 .

Thus we have shown G-W fermions realizing axial U(1)symmetry (U(1)_A symmetry) with a non-onsite symmetry transformation. While the left and right chiral symmetry U(1)_L and U(1)_R mixes between the linear combination of vector $U(1)_V$ symmetry and axial $U(1)_A$ symmetry, so $U(1)_L$ and $U(1)_R$ have non-onsite symmetry transformations, too. In short,

The axial $U(1)_A$ symmetry in G-W fermion is a nononsite symmetry. Also the left and right chiral symmetry $U(1)_L$ and $U(1)_R$ in G-W fermion are non-onsite symmetry.

The non-onsite symmetry here indicates the non-trivial edge states of bulk SPT, ^{29,37,38} thus Ginsparg-Wilson fermions can be regarded as gapless edge states of some bulk fermionic SPT order. With the above analysis, we emphasize again that our approach in the main text is different from Ginsparg-Wilson fermions while our approach implements only onsite symmetry, Ginsparg-Wilson fermion implements non-onsite symmetry. In Chen-Giedt-Poppitz model,²⁵ the Ginsparg-Wilson fermion is implemented. Thus this is one of the major differences between Chen-Giedt-Poppitz and our approaches.

Appendix C: Proof: Boundary Fully Gapping Rules \rightarrow Anomaly Matching Conditions

Here we show that if boundary states can be fully gapped (there exists a boundary gapping lattice Γ^{∂} satisfies boundary fully gapping rules (1)(2)(3) in Sec.IV C^{39,41,42,48,50}) with U(1) symmetry unbroken, then the boundary theory is an anomaly-free theory free from ABJ's U(1) anomaly. This theory satisfies the effective Hall conductance $\sigma_{xy}=0$, so the anomaly factor $\mathcal{A}=0$ by Eq.(42) in Sec.IV B, and illustrated in Fig.10.

FIG. 10: Feynman diagrams with solid lines representing chiral fermions and wavy lines representing U(1) gauge bosons: 1+1D chiral fermionic anomaly shows $\mathcal{A} = \sum (q_L^2 - q_R^2)$. For a generic 1+1D theory with U(1) symmetry, $\mathcal{A} = q^2 \mathbf{t} K^{-1} \mathbf{t}$.

Importantly, for N numbers of 1+1D Weyl fermions, in order to gap out the mirrored sector, our model enforces $N \in 2\mathbb{Z}^+$ is an even positive integer, and requires equal numbers of left/right moving modes $N_L = N_R = N/2$. When there is no interaction, we have a total $\mathrm{U}(1)^N$ symmetry for the free theory. We will then introduce the properly-designed gapping terms, and (if and only if) there are N/2 allowed gapping terms. The total symmetry is further broken from $\mathrm{U}(1)^N$ down to $\mathrm{U}(1)^{N/2}$ due to N/2 gapping terms.

The remained $U(1)^{N/2}$ symmetry stays unbroken for the following reasons:

(i) The gapping terms obey the $\mathrm{U}(1)^{N/2}$ symmetry. The symmetry is thus **not explicitly broken**.

(ii) In 1+1D, there is **no spontaneous symmetry breaking** of a continuous symmetry (such as our U(1) symmetry) due to Coleman-Mermin-Wagner-Hohenberg theorem.

(iii) We explicitly check the ground degeneracy of our model with a gapped boundary has a unique ground state, following the procedure of Ref.41,46. Thus, a unique ground state implies that there is no way to have spontaneous symmetry breaking.

Below we will prove that all the remained $U(1)^{N/2}$ symmetry is anomaly-free and mixed-anomaly-free. We will prove for both fermionic and bosonic cases together, under Chern-Simons symmetric-bilinear K matrix notation, with fermions $K = K^f$ and bosons $K = K^{b0}$, where $K = K^{-1}$.

Proof: There are N/2 linear-independent terms of ℓ_a for $\cos(\ell_a \cdot \Phi)$ in the boundary gapping terms Γ^{∂} , for $\{\ell_a\} = \{\ell_1, \ell_2, \dots, \ell_{N/2}\} \in \Gamma^{\partial}$. To find the remained unbroken $\mathrm{U}(1)^{N/2}$ symmetry, we notice that we can define charge vectors

$$\mathbf{t}_a \equiv K^{-1} \ell_a \tag{C1}$$

where any $\ell_a \in \Gamma^{\partial}$ is allowed, and $a=1,\ldots,N/2$. So there are totally N/2 charge vectors. These \mathbf{t}_a charge

vectors are linear-independent because all ℓ_a are linear-independent to each other.

Now we show that these N/2 charged vectors \mathbf{t}_a span the whole unbroken $\mathrm{U}(1)^{N/2}$ -symmetry. Indeed, follow the condition Eq.(30), this is true:

$$\ell_{c,I} \cdot \mathbf{t}_a = \ell_c K^{-1} \ell_a = 0 \tag{C2}$$

for all $\ell_c \in \Gamma^{\partial}$. This proves that N/2 charged vectors \mathbf{t}_a are exactly the $\mathrm{U}(1)^{N/2}$ -symmetry generators. We end the proof by showing our construction is indeed an anomaly-free theory among all $\mathrm{U}(1)^{N/2}$ -symmetries or all $\mathrm{U}(1)$ charge vectors \mathbf{t}_a , thus we check that they satisfy the anomaly matching conditions:

$$\mathcal{A}_{(a,b)} = 2\pi\sigma_{xy,(a,b)} = q^2\mathbf{t}_aK\mathbf{t}_b = q^2\ell_aK^{-1}\ell_b = 0.$$
 (C3)

Here $\ell_a,\ell_b \in \{\ell_1,\ell_2,\dots,\ell_{N/2}\}$, where we use $K=K^{-1}$. Therefore, our $\mathrm{U}(1)^{N/2}$ -symmetry theory is **fully anomaly-free** $(\mathcal{A}_{(a,a)}=0)$ and **mixed anomaly-free** $(\mathcal{A}_{(a,b)}=0 \text{ for } a\neq b)$. We thus proved

Theorem: The boundary fully gapping rules of 1+1D boundary/2+1D bulk with unbroken U(1) symmetry \rightarrow ABJ's U(1) anomaly matching condition in 1+1D.

for both fermions $K = K^f$ and bosons $K = K^{b0}$. (Q.E.D.)

Appendix D: Proof: Anomaly Matching Conditions \rightarrow Boundary Fully Gapping Rules

Here we show that if the boundary theory is an anomaly-free theory (free from ABJ's U(1) anomaly), which satisfies the anomaly factor $\mathcal{A}=0$ (i.e. the effective Hall conductance $\sigma_{xy}=0$ in the bulk, in Sec.IV B), then boundary states can be fully gapped with U(1) symmetry unbroken. Given a charged vector \mathbf{t} , we will prove in the specific case of U(1) symmetry, by finding the set of boundary gapping lattice Γ^{∂} satisfies boundary fully gapping rules $(\mathbf{1})(\mathbf{2})(\mathbf{3})$ in Sec.IV C. 39,41,42,48,50 We denote the charge vector as $\mathbf{t}=(t_1,t_2,t_3,\ldots,t_N)$. We will prove this for fermions $K=K^f$ and bosons $K=K^{b0}$ separately. Note the fact that $K=K^{-1}$ for both K^f and K^{b0} .

1. Proof for fermions $K = K^f$

Given a N-component charge vector

$$\mathbf{t} = (t_1, t_2, \dots, t_N) \tag{D1}$$

of a U(1) charged anomaly-free theory satisfying $\mathcal{A} = 0$, which means $\mathbf{t}(K^f)^{-1}\mathbf{t} = 0$. Here the fermionic K^f matrix is written in this canonical form,

$$K_{N\times N}^f = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \oplus \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \oplus \dots$$
 (D2)

We now construct Γ^{∂} obeying boundary fully gapping rules. We choose

$$\ell_1 = (K^f)\mathbf{t} \tag{D3}$$

which satisfies self-null condition $\ell_1(K^f)^{-1}\ell_1 = 0$. To complete the proof, we continue to find out a total set of $\ell_1, \ell_2, \dots, \ell_{N/2}$, so Γ^{∂} is a dimension N/2 Chern-Simonscharge lattice (Lagrangian subgroup).

For ℓ_2 , we choose its form as

$$\ell_2 = (\ell_{2,1}, \ell_{2,1}, \ell_{2,3}, \ell_{2,3}, 0, \dots, 0) \tag{D4}$$

where even component of ℓ_2 duplicates its odd component value, to satisfy $\ell_2(K^f)^{-1}\ell_1 = \ell_2(K^f)^{-1}\ell_2 = 0$. The second constraint is automatically true for our choice of ℓ_2 . The first constraint is achieved by solving $\ell_{2,1}(t_1-t_2)+\ell_{2,3}(t_3-t_4)=0$. We can properly choose ℓ_2 to satisfy this constraint.

For ℓ_n , by mathematical induction, we choose its form as

$$\ell_n = (\ell_{n,1}, \ell_{n,1}, \ell_{n,3}, \ell_{n,3}, \dots, \ell_{n,2n-1}, \ell_{n,2n-1}0, \dots, 0)$$
(D5)

where even component of ℓ_n duplicates its odd component value, to satisfy

$$\ell_n(K^f)^{-1}\ell_j, \quad j = 1, \dots, n,$$
 (D6)

for any n. For $2 \le j \le n$, the constraint is automatically true for our choice of ℓ_n and ℓ_j . For $\ell_n(K^f)^{-1}\ell_1=0$, it leads to the constraint: $\ell_{n,1}(t_1-t_2)+\ell_{n,3}(t_3-t_4)+\cdots+\ell_{n,2n-1}(t_{2n-1}-t_{2n})=0$, we can generically choose $\ell_{n,2n-1}\ne 0$ to have a new ℓ_n independent from other ℓ_j with $1\le j\le n-1$.

Notice the gapping term obeys U(1) symmetry, because $\ell_n \cdot \mathbf{t} = \ell_n (K^f)^{-1} \ell_1 = 0$ is always true for all ℓ_n . Thus we have constructed a dimension N/2 Lagrangian subgroup $\Gamma^{\partial} = \{\ell_1, \ell_2, \dots, \ell_{N/2}\}$ which obeys boundary fully gapping rules $(\mathbf{1})(\mathbf{2})(\mathbf{3})$ in Sec.IV C. (Q.E.D.)

2. Proof for bosons $K = K^{b0}$

Similar to the proof of fermion, we start with a given N-component charge vector \mathbf{t} ,

$$\mathbf{t} = (t_1, t_2, \dots, t_N),\tag{D7}$$

of a U(1) charged anomaly-free theory satisfying $\mathcal{A} = 0$, which means $\mathbf{t}(K^{b0})^{-1}\mathbf{t} = 0$.

Here the bosonic K^{b0} matrix is written in this canonical form,

$$K_{N\times N}^{b0} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \oplus \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \oplus \dots$$
 (D8)

We now construct Γ^{∂} obeying boundary fully gapping rules. We choose

$$\ell_1 = (K^{b0})\mathbf{t} \tag{D9}$$

which satisfies self-null condition $\ell_1(K^{b0})^{-1}\ell_1 = 0$. To complete the proof, we continue to find out a total set of $\ell_1, \ell_2, \dots, \ell_{N/2}$, so Γ^{∂} is a dimension N/2 Chern-Simonscharge lattice (Lagrangian subgroup).

For ℓ_2 , we choose its form as

$$\ell_2 = (\ell_{2,1}, 0, \ell_{2,3}, 0, \dots, 0) \tag{D10}$$

where even components of ℓ_2 are zeros, to satisfy $\ell_2(K^{b0})^{-1}\ell_1 = \ell_2(K^{b0})^{-1}\ell_2 = 0$. The second constraint is automatically true for our choice of ℓ_2 . The first constraint is achieved by $\ell_{2,1}(t_1) + \ell_{2,3}(t_3) = 0$. We can properly choose ℓ_2 to satisfy this constraint.

For ℓ_n , by mathematical induction, we choose its form

$$\ell_n = (\ell_{n,1}, 0, \ell_{n,3}, 0, \dots, \ell_{n,2n-1}, 0, \dots, 0)$$
 (D11)

where even components of ℓ_n are zeros, to satisfy

$$\ell_n(K^{b0})^{-1}\ell_j, \quad j = 1, \dots, n,$$
 (D12)

for any n. For $2 \leq j \leq n$, the constraint is automatically true for our choice of ℓ_n and ℓ_j . For $\ell_n(K^{b0})^{-1}\ell_1=0$, it leads to the constraint: $\ell_{n,1}(t_1)+\ell_{n,3}(t_3)+\ldots\ell_{n,2n-1}(t_{2n-1})=0$, we can generically choose $\ell_{n,2n-1}\neq 0$ to have a new ℓ_n independent from other ℓ_j with $1\leq j\leq n-1$.

Notice the gapping term obeys U(1) symmetry, because $\ell_n \cdot \mathbf{t} = \ell_n (K^{b0})^{-1} \ell_1 = 0$ is always true for all ℓ_n . Thus we have constructed a dimension N/2 Lagrangian subgroup $\Gamma^{\partial} = \{\ell_1, \ell_2, \dots, \ell_{N/2}\}$ which obeys boundary fully gapping rules $(\mathbf{1})(\mathbf{2})(\mathbf{3})$ in Sec.IV C. (Q.E.D.)

Theorem: ABJ's U(1) anomaly matching condition in $1+1D \rightarrow$ the boundary fully gapping rules of 1+1D boundary/2+1D bulk with unbroken U(1) symmetry.

We emphasize again that although we start with a single U(1) anomaly-free theory (aiming for a single U(1)-symmetry), it turns out that the full symmetry after adding interacting gapping terms will result in a theory with an enhanced total U(1) $^{N/2}$ symmetry. The N/2 number of gapping terms break a total U(1) N symmetry (for N free Weyl fermions) down to U(1) $^{N/2}$ symmetry. The derivation follows directly from the statement in Appendix C, which we shall not repeat it.

We comment that our proofs in Appendix C and D are algebraic and topological, thus it is a non-perturbative result (instead of a perturbative result in the sense of doing weak or strong coupling expansions).

Appendix E: More about the Proof of "Boundary Fully Gapping Rules"

This section aims to demonstrate that the **Boundary Fully Gapping Rules** used throughout our work (and also used in Ref), indeed can gap the edge states. We discuss this proof here to make our work self-contained and to further convince the readers.

1. Canonical quantization

Here we set up the canonical quantization of the bosonic field ϕ_I for a multiplet chiral boson theory of Eq.(22) on a 1+1D spacetime, with a spatial S^1 compact circle. The canonical quantization means that imposing a commutation relation between ϕ_I and its conjugate momentum field $\Pi_I(x) = \frac{\delta L}{\delta(\partial_I \phi_I)} = \frac{1}{2\pi} K_{IJ} \partial_x \phi_J$. Since ϕ_I is

a compact phase of a matter field, its bosonization contains both zero mode ϕ_{0I} and winding momentum P_{ϕ_J} , in addition to Fourier modes $\alpha_{I,n}$:⁴¹

$$\Phi_I(x) = \phi_{0I} + K_{IJ}^{-1} P_{\phi_J} \frac{2\pi}{L} x + i \sum_{n \neq 0} \frac{1}{n} \alpha_{I,n} e^{-inx \frac{2\pi}{L}}.$$
 (E1)

The periodic boundary has a size of length $0 \le x < L$, with x identified with x + L. We impose the commutation relation for zero modes and winding modes, and generalized Kac-Moody algebra for Fourier modes:

$$[\phi_{0I}, P_{\phi_I}] = i\delta_{IJ}, \ [\alpha_{I,n}, \alpha_{J,m}] = nK_{II}^{-1}\delta_{n,-m}.$$
 (E2)

Consequently, the commutation relations for the canonical quantized fields are:

$$[\phi_I(x_1), K_{I'J}\partial_x\phi_J(x_2)] = 2\pi i \delta_{II'}\delta(x_1 - x_2), \quad (E3)$$
$$[\phi_I(x_1), \Pi_J(x_2)] = i \delta_{IJ}\delta(x_1 - x_2). \quad (E4)$$

2. Approach I: Mass gap for gapping zero energy modes

We provide the first approach to show that the anomaly-free edge states can be gapped under the properly-designed gapping terms. Here we explicitly calculate the mass gap for the zero energy mode and its higher excitations. The generic theory is

$$S_{\partial} = \frac{1}{4\pi} \int dt \, dx \, (K_{IJ}\partial_t \Phi_I \partial_x \Phi_J - V_{IJ}\partial_x \Phi_I \partial_x \Phi_J)$$

+
$$\int dt \, dx \, \sum_a g_a \cos(\ell_{a,I} \cdot \Phi_I).$$
 (E5)

We will consider the even-rank symmetric K matrix, so the full edge theory has an even number of modes and thus potentially be gappable. In the following we shall determine under what conditions that the edge states can obtain a mass gap. Imagining at the large coupling g, the Φ_I field get trapped at the minimum of the cosine potential with small fluctuations. We will perform an expansion of $\cos(\ell_{a,I}\cdot\Phi_I)\simeq 1-\frac{1}{2}(\ell_{a,I}\cdot\Phi_I)^2+\ldots$ to a quadratic order and see what it implies about the mass gap. We can diagonalize the Hamiltonian,

$$H \simeq \left(\int_0^L dx \ V_{IJ} \partial_x \Phi_I \partial_x \Phi_J \right) + \frac{1}{2} \sum_a g_a (\ell_{a,I} \cdot \Phi_I)^2 L + \dots$$
(Ec.)

under a complete Φ mode expansion, and find the energy spectra for its eigenvalues. To summarize the result, we find that:

(E-1). If and only if we include all the gapping terms allowed by **Boundary Full Gapping Rules**, we can open the mass gap of zero modes (n=0) as well as Fourier modes (non-zero modes $n \neq 0$). Namely, the energy spectrum is in the form of

$$E_n = \left(\sqrt{\Delta^2 + \#(\frac{2\pi n}{L})^2} + \dots\right),$$
 (E7)

where Δ is the mass gap. Here we emphasize the energy of Fourier modes $(n \neq 0)$ behaves towards zero modes at long wave-length low energy limit $(L \to \infty)$. Such spectra become continuous at $L \to \infty$ limit, which is the expected energy behavior.

(E-2). If we include the *incompatible* Wilson line operators, such as ℓ and ℓ' where $\ell K^{-1}\ell' \neq 0$, while the interaction terms contain *incompatible* gapping terms $g\cos(\ell \cdot \Phi) + g'\cos(\ell' \cdot \Phi)$, we find the *unstable* energy spectra

$$E_n = \left(\sqrt{\Delta^2 + \#(\frac{2\pi n}{L})^2 + g g'(\frac{L}{n})^2 \cdots + \dots} + \dots\right),$$
(E8)

The energy spectra shows an instability of the system, because at low energy limit $(L \to \infty)$, the spectra become discontinuous (from n=0 to $n \neq 0$) and jump to infinity as long as there are incompatible gapping terms(namely, $g \cdot g' \neq 0$). Such disastrous behavior of $(L/n)^2$ implies the quadratic expansion analysis may not account for the whole physics. In that case, the disastrous behavior invalidates the trapping of Φ field at a local minimum, thus invalidates the mass gap, and the unstable system potentially seeks to be gapless phases.

Below we demonstrate the result explicitly for the simplest rank-2 K matrix, while the case for higher rank K matrix can be straightforwardly generalized. The most general rank-2 K matrix is

$$K \equiv \begin{pmatrix} k_1 & k_3 \\ k_3 & k_2 \end{pmatrix} \equiv \begin{pmatrix} k_1 & k_3 \\ k_3 & (k_3^2 - p^2)/k_1 \end{pmatrix}, \quad V = \begin{pmatrix} v_1 & v_2 \\ v_2 & v_1 \end{pmatrix},$$
(E9)

while the V velocity matrix is chosen to be rescaled as the above. (Actually the V matrix is immaterial to our conclusion.) Our discussion below holds for both $k_3=\pm |k_3|$ cases. We define $k_2=(k_3^2-p^2)/k_1$, so that $\det(K)=-p^2$ We find that only when

$$\sqrt{|\det(K)|} \equiv p \in \mathbb{Z},$$

p is an integer, we can find gapping terms allowed by Boundary Fully Gapping Rules. (A side comment is that $\det(K) = -p^2$ implies its bulk can be constructed as a quantum double or a twisted quantum double model on the lattice.) For the above rank-2 K matrix, we find two independent sets, $\{\ell_1 = (\ell_{1,1}, \ell_{1,2})\}$ and $\{\ell'_1 = (\ell'_{1,1}, \ell'_{1,2})\}$, each set has only one ℓ vector. Here the ℓ vector is written as $\ell_{a,I}$, with the index a labeling the a-th (linear independent) ℓ vector in the Lagrangian subgroup, and the index I labeling the I-component of the ℓ_a vector. Their forms are:

$$\frac{\ell_{1,1}}{\ell_{1,2}} = \frac{k_1}{k_3 + p} = \frac{k_3 - p}{k_2},\tag{E10}$$

$$\frac{\ell'_{1,1}}{\ell'_{1,2}} = \frac{k_1}{k_3 - p} = \frac{k_3 + p}{k_2}.$$
 (E11)

We denote the cosine potentials spanned by these ℓ_1 , ℓ'_1 vectors in Eq.(E5) as:

$$g\cos(\ell_1 \cdot \Phi) + g'\cos(\ell'_1 \cdot \Phi).$$
 (E12)

From our understanding of Boundary Full Gapping Rules, these two $\ell_1,\,\ell_1'$ vectors are not compatible to each

other. In this sense, we shall not include both terms if we aim to fully gap the edge states.

Now we focus on computing the mass gap of our interests for the bosonic K matrix $K^b_{2\times 2}=\begin{pmatrix} 0&1\\1&0\end{pmatrix}$ and the fermionic K matrix $K^f_{2\times 2}=\begin{pmatrix} 1&0\\0&-1\end{pmatrix}$. We use both

the Hamiltonian or the Lagrangian formalism to extract the energy, for both zero modes (n=0) and Fourier modes (non-zero modes $n \neq 0$). For both the Hamiltonian and Lagrangian formalisms, we obtain the consistent result for energy gaps E_n :

1st Case: Bosonic $K_{2\times 2}^b = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$:

$$E_n = \sqrt{2\pi(g+g')v_1 + (\frac{2\pi n}{L})^2 v_1^2 + g g'(\frac{L}{n})^2} \pm (\frac{2\pi n}{L})v_2$$
 (E13)

2nd Case: Fermionic $K_{2\times 2}^f = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$:

$$E_n = \sqrt{4\pi g(v_1 - v_2) + 4\pi g'(v_1 + v_2) + (\frac{2\pi n}{L})^2 (v_1^2 - v_2^2) + (\frac{2L}{n})^2 g g'}$$
 (E14)

Logically, for a rank-2 K matrix, we have shown that:

- If we include the gapping terms allowed by Boundary Full Gapping Rules, either (i) $g \neq 0, g' = 0$, or (ii) $g = 0, g' \neq 0$, then we have the *stable* form of the mass gap in Eq.(E7). Thus we show the *if*-statement in (E-1).
- If we include incompatible interaction terms (here $\ell_1 K^{-1} \ell'_1 \neq 0$), such that both $g \neq 0$ and $g' \neq 0$, then the energy gap is of the *unstable* form in Eq.(E8). Thus we show the statement in (E-2).
- Meanwhile, this (E-2) implies that if we include *more* interaction terms allowed by Boundary Full Gapping Rules, we have an unstable energy gap, thus it may drive the system to the gapless states due to the instability. Moreover, if we include *less* interaction terms allowed by Boundary Full Gapping Rules (i.e. if we do not include all allowed *compatible* gapping terms), then we cannot fully gap the edge states (For 1-left-moving mode and 1-right-moving mode, we need at least 1 interaction term to gap the edge.) Thus we also show the *only-if*-statement in (E-1).

This approach work for a generic even-rank K matrix thus can be applicable to show the above statements (E-1) and (E-2) hold in general. More generally, for rank-N K matrix Chern-Simons theory, with the boundary N/2-left-moving modes and N/2-right-moving modes, we need at least and at most N/2-linear-independent interaction terms to gap the edge. If one includes more terms than the allowed terms (such as the numerical attempt in Ref.25), it may drive the system to the gapless states due to the instability from the unwanted quantum fluctuation. This can be one of the reasons why Ref.25 fails to achieve gapless fermions by gapping mirror-fermions.

3rd Case: General even-rank K matrix: Here we outline another view of the energy-gap-stability for the edge states, for a generic rank-N K matrix Chern-Simons theory with multiplet-chiral-boson-theory edge states. We include the full interacting cosine term for

the lowest energy states - zero and winding modes:

$$\cos(\ell_{a,I} \cdot \Phi_I) \to \cos(\ell_{a,I} \cdot (\phi_{0I} + K_{IJ}^{-1} P_{\phi_J} \frac{2\pi}{L} x)), \text{ (E15)}$$

while we drop the higher energy Fourier modes. (Note when $L \to \infty$, the kinetic term $H_{kin} = \frac{(2\pi)^2}{4\pi L} V_{IJ} K_{Il1}^{-1} K_{Jl2}^{-1} P_{\phi_{l1}} P_{\phi_{l2}}$ has an order O(1/L) so is negligible, thus the cosine potential Eq. (E15) dominates. Though to evaluate the mass gap, we keep both kinetic and potential terms.) The stability of the mass gap can be understood from under what conditions we can safely expand the cosine term to extract the leading quadratic terms by only keeping the zero modes via $\cos(\ell_{a,I} \cdot \Phi_I) \simeq 1 - \frac{1}{2} (\ell_{a,I} \cdot \phi_{0I})^2 + \dots$ (If one does not decouple the winding mode term, there is a complicated x dependence in $P_{\phi_J} \frac{2\pi}{L} x$ along the x integration.) The challenge for this cosine expansion is rooted in the noncommuting algebra from $[\phi_{0I}, P_{\phi_J}] = \mathrm{i}\delta_{IJ}$. This can be resolved by requiring $\ell_{a,I}\phi_{0I}$ and $\ell_{a,I'}K_{I'J}^{-1}P_{\phi_J}$ commute in Eq.(E15),

$$\begin{aligned} [\ell_{a,I}\phi_{0I},\;\ell_{a,I'}K_{I'J}^{-1}P_{\phi_J}] \;&=\; \ell_{a,I}K_{I'J}^{-1}\ell_{a,I'}\;(\mathrm{i}\delta_{IJ}) \\ &=\; (\mathrm{i})(\ell_{a,J}K_{I'J}^{-1}\ell_{a,I'}) = 0. \end{aligned}$$

This is indeed the Boundary Full Gapping Rules (1), the trivial statistics rule among the Wilson line operators for the gapping terms. Under this commuting condition (we can interpret that there is no unwanted quantum fluctuation), we can thus expand Eq.(E15) using the trigonometric identity for c-numbers as

$$\cos(\ell_{a,I}\phi_{0I})\cos(\ell_{a,I}K_{IJ}^{-1}P_{\phi_{J}}\frac{2\pi}{L}x) - \sin(\ell_{a,I}\phi_{0I})\sin(\ell_{a,I}K_{IJ}^{-1}P_{\phi_{J}}\frac{2\pi}{L}x)$$
 (E17)

and then we safely integrate over L. Note that both $\cos(\dots x)$ and $\sin(\dots x)$ are periodic in the region [0,L), so both x-integrations vanish unless when $\ell_{a,I} \cdot K_{IJ}^{-1} P_{\phi_J} =$

0 such that $\cos(\ell_{a,I}K_{IJ}^{-1}P_{\phi_J}\frac{2\pi}{L}x)=1$. We thus obtain

$$g_a \int_0^L dx \, \text{Eq.}(E15) = g_a L \, \cos(\ell_{a,I} \cdot \phi_{0I}) \delta_{(\ell_{a,I} \cdot K_{IJ}^{-1} P_{\phi_J}, 0)}.$$
(E18)

The Kronecker-delta-condition $\delta_{(\ell_{a,I},K_{IJ}^{-1}P_{\phi_J},0)}=1$ implies that there is a nonzero value if and only if $\ell_{a,I}$. $K_{IJ}^{-1}P_{\phi_J}=0$. This is also consistent with the *Chern-Simons quantized lattice* as the Hilbert space of the ground states. Here P_{ϕ} forms a discrete quantized lattice because its conjugate ϕ_0 is periodic. This result can be applied to count the ground state degeneracy of Chern-Simons theory on a closed manifold or a compact manifold with gapped boundaries. 41,46

In short, we have shown that when $\ell^T K^{-1} \ell = 0$, we have the desired cosine potential expansion via the zero mode quadratic expansion at large g_a coupling, $g_a \int_0^L dx \cos(\ell_{a,I} \cdot \Phi_I) \simeq -g_a L \frac{1}{2} (\ell_{a,I} \cdot \phi_{0I})^2 + \dots$ The nonzero mass gaps of zero modes can be readily shown by solving the quadratic simple harmonic oscillators of both the kinetic and the leading-order of the potential terms:

$$\frac{(2\pi)^2}{4\pi L} V_{IJ} K_{Il1}^{-1} K_{Jl2}^{-1} P_{\phi_{l1}} P_{\phi_{l2}} + \sum_{a} g_a L_{\frac{1}{2}} (\ell_{a,I} \cdot \phi_{0I})^2$$
 (E19)

The mass gap is independent of the system size, the order one finite gap

$$\Delta \simeq O(\sqrt{2\pi g_a \ell_{a,l1} \ell_{a,l2} V_{IJ} K_{Il1}^{-1} K_{Jl2}^{-1}}),$$
 (E20)

which the mass matrix can be properly diagonalized, since there are only conjugate variables ϕ_{0I} and $P_{\phi,J}$ in the quadratic order.

We again find that the above statements consistent with (E-1) and (E-2) for a generic even-rank K matrix.

3. Mass Gap for Klein-Gordon fields and non-chiral Luttinger liquids under sine-Gordon potential

First, we recall the two statements (E-3),(E-4) that:

(E-3) A scalar boson theory of a Klein-Gordon action with a sine-Gordon potential:

$$S_{\partial} = \int dt \, dx \, \frac{\kappa}{2} (\partial_t \varphi \partial_t \varphi - \partial_x \varphi \partial_x \varphi) + g \cos(\beta \varphi).$$
 (E21)

at strong coupling g can induce the mass gap for the scalar mode φ .

(E-4) A non-chiral Luttinger liquids (non-chiral in the sense of equal left-right moving modes, but can have U(1)-charge-chirality with respect to a U(1) symmetry) with ϕ and θ dual scalar fields with a sine-Gordon potential for ϕ field:

$$S_{\partial} = \int dt \, dx \, \left(\frac{1}{4\pi} ((\partial_t \phi \partial_x \theta + \partial_x \phi \partial_t \theta) - V_{IJ} \partial_x \Phi_I \partial_x \Phi_J) + g \cos(\beta \, \theta) \right). \tag{E22}$$

at strong coupling g can induce the mass gap for *all* the scalar mode $\Phi \equiv (\phi, \theta)$.

Indeed, the statement **(E-3)** and **(E-4)** are related because Eq.(E21) and Eq.(E22) are identified by the canonical conjugate momentum relation:

$$\partial_t \phi \sim \partial_x \theta, \quad \partial_t \theta \sim \partial_x \phi,$$
 (E23)

up to a normalization factor and up to some Euclidean time transformation.

There are immense and broad amount of literatures demonstrating (E-3),(E-4) are true, and we recommend to look for Ref.55,89,90. Here we summarize several aspects of these understandings for our readers:

ullet 1. The **(E-3)**'s quantum sine-Gordon action of Eq.(E21) is equivalent to the massive Thirring model:

$$S_{MT} = \int dt \, dx (i\bar{\psi}\gamma^{\mu}\partial_{\mu}\psi - \frac{\lambda}{2}(\bar{\psi}\gamma^{\mu}\psi)(\bar{\psi}\gamma_{\mu}\psi) - m\bar{\psi}\psi)$$
(E24)

via the identification $(j^{\mu} \equiv \bar{\psi}\gamma^{\mu}\psi)$:

$$\frac{4\pi\kappa}{\beta^2} = 1 + \frac{\lambda}{\pi}, \ j^{\mu} = \frac{-\beta}{2\pi} \epsilon^{\mu\nu} \partial_{\nu} \varphi, \ g\cos(\beta\varphi) = -m\bar{\psi}\psi. (E25)$$

One can compute the induced mass m of scalar field φ , from the Zamolodchikov formula, 91,92 which coincides with the lightest bound state of soliton-antisoliton (the first breather), expressed in terms of a soliton of mass M via:

$$m \sim 2M \sin(\frac{\pi}{2} \frac{\beta^2}{(8\pi - \beta^2)}), \tag{E26}$$

and the soliton mass M is determined by g, β :

$$g \sim \frac{2\Gamma(\frac{\beta^2}{8\pi})}{\pi\Gamma(1 - \frac{\beta^2}{8\pi})} \left(M \frac{\sqrt{\pi}\Gamma(\frac{1}{2} + \frac{\beta^2}{2(8\pi - \beta^2)})}{2\Gamma(\frac{\beta^2}{2(8\pi - \beta^2)})}\right)^{2 - \frac{\beta^2}{4\pi}}.$$
 (E27)

On the other hand, the sine-Gordon action is an integrable model, and can be also studied by Bethe ansatz. By all means, it is well-known that the two-point correlator exponentially decays, indicating the energy gap (or the mass gap) exists.

•2. Renormalization Group (RG) analysis on the sine-Gordon model of (E-4): It is known that the 2-dimensional XY model, neutral Coulomb gas, and sine-Gordon model, these three models describe the same universality class (up to some Euclidean time transformation from 1+1D to 2D). The 2-dimensional XY model with $J = \frac{1}{8\pi^2\kappa}$ matches the universality class of Eq.(E21) by a Hamiltonian

$$H_{xy} = -J \sum_{\langle i,j \rangle} \cos(\theta_i - \theta_j).$$
 (E28)

(1). **High Temperature Short-Range Order Phase:** Its high temperature phase (small *J*) has the exponential-decaying two-point spin-spin correlator

$$\langle \mathbf{S}(0)\mathbf{S}(r)\rangle \sim \langle \cos(\theta_0 - \theta_r)\rangle \sim (J/2)^{|r|} \sim \exp(-|r|/\xi).$$
 (E29)

with the correlation length

$$\xi = (\ln(2/J))^{-1} = (\ln(16\pi^2\kappa))^{-1}.$$
 (E30)

This high temperature phase of XY model is dual to the high temperature phase (small J) of the neutral Coulomb gas with a two dimensional logarithmic potential energy form:

$$-4\pi^2 J \sum_{i < J} n_i n_j \ln(r_i - r_j) + \dots$$
 (E31)

where n_i are the charge density $(n_i = \pm 1, \pm 2, ...,$ with the totally neutral charge), and ... are unwritten terms containing the core energy of charges and the core energy of smooth configurations without vortex singularity. The Coulomb gas at high T is the "metallic plasma phase," the Coulomb charge interaction is screened, thus the effective interaction becomes exponentially screening or decaying.

In short, at high temperature of XY model (small J, high T metallic plasma phase for Coulomb gas) the correlator of vortex configuration $\theta(r)$ is short-ranged and decays exponentially:

$$\langle e^{i\theta(0)}e^{-i\theta(r)}\rangle \sim \exp(-|r|/\xi).$$
 (E32)

It is worth noting that the correlation function measuring the interactions between charges is long ranged in an insulator phase (Coulomb law), it is exponentially correlating in a metallic phase (screening).

(2). Low Temperature Quasi Long-Range Order Phase: On the other hand, at low temperature phase (large J), the interaction is strong and the vortices are bound together as dipoles. The correlation function shows a quasi algebraic long-range order:

$$\langle \mathbf{S}(0)\mathbf{S}(r)\rangle \sim \langle e^{\mathrm{i}\theta(0)}e^{-\mathrm{i}\theta(r)}\rangle \sim (\frac{a}{|r|})^{\frac{1}{2\pi J}},$$
 (E33)

with a short-distance cutoff like lattice spacing a.

It can be also studied from the fermionization-bosonization language. The four-fermion interactions via the forward scattering term and the dispersion term can be bosonized to a free boson theory through changing the compactified radius of bosons The four-fermion interactions via the backward scattering term and the Umklapp scattering term can be bosonized to induce the cosine term, which can generate the mass gap at strong interaction (large g).

The above indicates that when the coupling g grows, the RG flows to a massive gapped phase, but those perturbation analyses are done by the perturbation from the free or the weak-coupling theory. Below we provide a new demonstration explicitly here from the strong-coupling fixed point.

•3. RG analysis at the strong-coupling fixed point: By assuming the perturbation is done on any of the

strong-coupling fixed point of gapped phases (there can be more than one fixed point of massive phases), we consider at the large coupling g, the scalar field is pinned down at the minimum of cosine potential, we thus will consider the dominant term as the $g\cos(\beta\varphi)$ on the discretized spatial lattice and only a continuous time:

$$\int dt \left(\sum_{i} \frac{1}{2} g(\varphi_i)^2 + \dots \right)$$
 (E34)

Setting this dominant term to be a marginal operator means the scaling dimension of φ_i is

$$[\varphi_i] = 1/2.$$

Any operator with $(\varphi_i)^n$ for n>2 is an irrelevant operator. The kinetic term can be generated by an operator:

$$e^{iP_{\varphi}a} \sim e^{ia\partial_x \varphi} \sim e^{i(\varphi_{i+1} - \varphi_j)}$$
 (E35)

where P is the conjugate momentum of the zero mode φ_0 and a is the lattice spacing, since $e^{\mathrm{i}P_{\varphi}a}$ generates the lattice translation by

$$e^{iP_{\varphi}a}\varphi_0e^{-iP_{\varphi}a} = \varphi_0 + a. \tag{E36}$$

But the kinetic term, which contains $e^{i(\varphi_{i+1}-\varphi_j)}$, has an *infinite scaling dimension* due to infinite power of φ fields. Thus it is *irrelevant* operator in the sense of RG at the strong-coupling fixed point.

We should remark that this above RG analysis at the strong-coupling fixed point shows the kinetic energy is irrelevant respect to the dominant $g\cos(\beta\varphi)$ potential, independent to the β value. This is remarkable because the RG analysis around the free theory fixed point has β value dependence. In particular, the scaling dimensions of the normal ordered : $\cos(\beta\varphi)$: of Eq.(E21) and : $\cos(\beta\theta)$:of Eq.(E22) is

$$[\cos(\beta\varphi)] = \frac{\beta^2}{4\pi\kappa}, \quad \cos(\beta\theta) = \frac{\beta^2}{2},$$

and the weak-coupling RG analysis shows that g flows to a large coupling g when $\frac{\beta^2}{4\pi\kappa} < 2$, $\frac{\beta^2}{2} < 2$. However, at non-perturbative strong-coupling (lattice-scale) regime, it is believed that the result is insensitive to β value. As we have shown from the strong-coupling fixed point analysis, we believe that the β -independence result is correct.

To summarize, we show that such an irrelevant operator of kinetic term cannot destroy the massive gapped phases at the strong-coupling fixed point, thus the mass gap remains robust, independent to the β value.

4. Approach II: Map the anomaly-free theory with gapping terms to the decoupled non-chiral Luttinger liquids with gapped spectrum

Here we provide the second approach to show that the anomaly-free edge states can be gapped under the properly-designed gapping terms. The key step is that we will map the N-component anomaly-free theory

with properly-designed gapping terms to N/2-decoupled-copies of non-chiral Luttinger liquids of the statement (E-4), each copy has the gapped spectrum. (This key step is logically the same as the proof in Appendix A of Ref.47.) Thus, by the equivalence mapping, we can prove that the anomaly-free edge states can be fully gapped. We include this proof 47 to make our claim self-contained. We again consider the generic theory of Eq.(E5):

$$S_{\partial}(\Phi, K, \{\ell_a\}) = \frac{1}{4\pi} \int dt \, dx \, (K_{IJ}\partial_t \Phi_I \partial_x \Phi_J - V_{IJ}\partial_x \Phi_I \partial_x \Phi_J) + \int dt \, dx \, \sum_a g_a \cos(\ell_{a,I} \cdot \Phi_I),$$

where Φ , K, $\{\ell_a\}$ are the data for this 1+1D action $S_{\partial}(\Phi,K,\{\ell_a\})$, while the velocity matrix is not universal and is immaterial to our discussion below. In Appendix D, we had shown that the N-component anomaly-free theory guarantees the N/2-linear independent gapping terms of boundary gapping lattice(Lagrangian subgroup) Γ^{∂} satisfying:

$$\ell_{a,I} K_{IJ}^{-1} \ell_{b,J} = 0 \tag{E37}$$

for any $\ell_a, \ell_b \in \Gamma^{\partial}$. In our case (both bosonic and fermionic theory), all the K is invertible due to $\det(K) \neq 0$, thus one can define a dual vector as in Ref.47, $\ell_{a,I} = K_{II'}\eta_{a,I'}$, such that Eq.(E37) becomes

$$\eta_{a,I'} K_{IJ} \eta_{b,J'} = 0.$$
(E38)

The data of action becomes $S_{\partial}(\Phi, K, \{\ell_a\}) \rightarrow S_{\partial}(\Phi, K, \{\eta_a\})$. In our proof, we will stick to the data $S_{\partial}(\Phi, K, \{\ell_a\})$. We can construct a $N \times (N/2)$ -component matrix \mathbf{L} :

$$\mathbf{L} \equiv \left(\ell_1, \ell_2, \dots, \ell_{N/2}\right) \tag{E39}$$

with N/2 column vectors, and each column vector is $\ell_1, \ell_2, \ldots, \ell_{N/2}$. We can write **L** base on the Smith normal form, so $\mathbf{L} = VDW$, with V is a $N \times N$ integer matrix and W is a $(N/2) \times (N/2)$ integer matrix. Both V and W have a determinant $\det(V) = \det(W) = 1$. The D is a $N \times (N/2)$ integer matrix:

$$D \equiv \begin{pmatrix} \bar{D} \\ 0 \end{pmatrix} \equiv \begin{pmatrix} d_1 & 0 & \dots & 0 \\ 0 & d_2 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \dots & d_{N/2} \\ \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \vdots & 0 \end{pmatrix}, \tag{E40}$$

with \bar{D} is a diagonal integer matrix. Since **L** has N/2-linear-independent column vectors, thus $\det(\bar{D}) \neq 0$, and all entries of \bar{D} are nonzero.

1st Mapping - We do a change of variables:

$$\begin{split} \Phi' &= V^T \Phi \\ \ell' &= V^{-1} \ell \\ K' &= V^{-1} K(V^T)^{-1} \\ S_{\partial}(\Phi, K, \{\ell_a\}) &\to S_{\partial}(\Phi', K', \{\ell'_a\}) \end{split}$$

This makes the L' form simpler:

$$\mathbf{L}' = V^{-1}\mathbf{L} = V^{-1}(VDW) = \begin{pmatrix} \bar{D}W\\0 \end{pmatrix}.$$
 (E41)

Here is the key step: due to Eq.(E37), we have the important equality,

$$\boxed{\mathbf{L}^T K^{-1} \mathbf{L} = 0},\tag{E42}$$

thus

$$(VDW)^T K^{-1} VDW = 0 (E43)$$

$$= W^T D^T K'^{-1} DW = 0 (E44)$$

$$=(\bar{D}W,0)K'^{-1}\begin{pmatrix}\bar{D}W\\0\end{pmatrix}=0$$
 (E45)

Hence, K'^{-1} can be written as the following four blocks of $N \times N$ matrices F, G (F, G can have fractional values):

$$K'^{-1} = \begin{pmatrix} 0 & F \\ F^T & G \end{pmatrix}, \tag{E46}$$

with $det(F) \neq 0$ and G is symmetric. Thus the integer K' matrix has the form

$$K' = \begin{pmatrix} -(\mathbf{F}^T)^{-1}\mathbf{G}\mathbf{F}^{-1} & (\mathbf{F}^T)^{-1} \\ \mathbf{F}^{-1} & 0 \end{pmatrix}.$$
 (E47)

We notice that,

Lemma 1: Due to K' matrix is an *integer* matrix, the three matrices $-(F^T)^{-1}GF^{-1}$, F^{-1} and $(F^T)^{-1}$ are *integer matrices*. Therefore, F, G can be *fractional matrices*.

2nd Mapping - To obtain the final mapping to N/2-decoupled-copies of non-chiral Luttinger liquids, we do another change of variables:

$$\Phi'' = U\Phi'
\ell'' = (U^{-1})^T \ell'
K'' = (U^T)^{-1} K'(U)^{-1}
S_{\partial}(\Phi', K', \{\ell'_a\}) \to S_{\partial}(\Phi'', K'', \{\ell''_a\})$$

With the goal in mind to make the new K matrix $K'' = (K'')^{-1} = \begin{pmatrix} 0 & \mathbf{1} \\ \mathbf{1} & 0 \end{pmatrix}$ and $\mathbf{1}$ is the $N \times N$ identity matrix. This constrains U, and we find

$$(K'')^{-1} = U(K')^{-1}U^T = \begin{pmatrix} 0 & \mathbf{1} \\ \mathbf{1} & 0 \end{pmatrix}$$
 (E48)

$$\Rightarrow U = \begin{pmatrix} -\frac{1}{2} (\mathbf{F}^T)^{-1} \mathbf{G} \mathbf{F}^{-1} & (\mathbf{F}^T)^{-1} \\ \mathbf{1} & 0 \end{pmatrix} \quad (E49)$$

Importantly, due to **Lemma 1**, we have $(F^T)^{-1}$ and $-(F^T)^{-1}GF^{-1}$ are *integer matrices*, so U is at most a matrix taking half-integer values(almost an integer matrix).

In the new Φ'' basis, we define the N-component column vector

$$\Phi'' = (\bar{\phi}_1, \bar{\phi}_2, \dots, \bar{\phi}_{N/2}, \bar{\theta}_1, \bar{\theta}_2, \dots, \bar{\theta}_{N/2}).$$

Based on Appendix \mathbf{E} 1, the canonical-quantization in the new basis becomes

$$[\Phi_{I}''(x_{1}), \partial_{x}\Phi_{J}''(x_{2})] = 2\pi i (K''^{-1})_{IJ}\delta(x_{1} - x_{2}),$$

$$[\bar{\phi}_{I}(x_{1}), \partial_{x}\bar{\phi}_{J}(x_{2})] = [\bar{\theta}_{I}(x_{1}), \partial_{x}\bar{\theta}_{J}(x_{2})] = 0,$$

$$[\bar{\phi}_{I}(x_{1}), \partial_{x}\bar{\theta}_{J}(x_{2})] = 2\pi i \delta_{IJ}\delta(x_{1} - x_{2}).$$
 (E50)

This is exactly what we aim for the decoupled non-chiral Luttinger liquids as the form of N/2-copies of (E-4). However, the cosine potential in the new basis is not yet fully decoupled due to

$$\begin{split} & \ell''^T \Phi'' = \ell^T (V^{-1})^T (U^{-1}) \Phi'' \\ \Rightarrow & \mathbf{L}''^T = \mathbf{L}^T (V^{-1})^T (U^{-1}) = (W^T D^T) (U^{-1}) \\ \Rightarrow & \mathbf{L}''^T = \left(W^T \bar{D}, 0\right) \begin{pmatrix} 0 & \mathbf{1} \\ \mathbf{F}^T & \frac{1}{2} \mathbf{G} \mathbf{F}^{-1} \end{pmatrix} = \left(0, W^T \bar{D}\right). \end{split}$$

We obtain the cosine potential term as

$$g_a \cos(\ell_{a,I} \cdot \Phi_I) = g_a \cos(W_{Ja} d_J \bar{\theta}_J).$$
 (E51)

If W_{Ja} is a diagonal matrix, the non-chiral Luttinger liquids are decoupled into N/2-copies also in the interacting potential terms. In general, $W_{Ja}d_J$ may not be diagonal, but the charge quantization and the large coupling g_a of the cosine potentials cause

$$\sum_{J} W_{Ja} d_{J} \bar{\theta}_{J} = 2\pi n_{I}, \quad I = 1, \dots, N/2, \quad n_{I} \in \mathbb{Z}$$

locked to the minimum value. Equivalently, due to both W and W^{-1} are integer matrices with $\det(W)=1$, we have

$$d_J \bar{\theta}_J = 2\pi n'_J, \quad J = 1, \dots, N/2, \quad n'_J \in \mathbb{Z}.$$
 (E52)

The last step is to check the constraint on the $\bar{\phi}_I$ and $\bar{\theta}_J$. The original particle number quantization constraint changes from $\frac{1}{2\pi} \int_0^L \partial_x \Phi_I = \zeta_I$ with an integer $\zeta_I \in \mathbb{Z}$, to

$$\begin{cases} \int_{0}^{L} \frac{\partial_{x} \bar{\phi}_{I}}{2\pi} = -\frac{1}{2} ((\mathbf{F}^{T})^{-1} \mathbf{G} \mathbf{F}^{-1} V^{T})_{Ij} \zeta_{j} + \sum_{j=1}^{N/2} (\mathbf{F}^{T})_{I,j}^{-1} \zeta_{N/2+j} \\ \int_{0}^{L} \frac{\partial_{x} \bar{\theta}_{I}}{2\pi} = \sum_{j=1}^{N/2} V_{I,I+j}^{T} \zeta_{j} \end{cases}$$
(E5)

Again, from **Lemma 1**, we have $(F^T)^{-1}$ and $-(F^T)^{-1}GF^{-1}$ are integer matrices, and V is an integer matrix, so at least the particle number quantization of $\int_0^L \frac{\partial_x \bar{\phi}_I}{2\pi}$ takes as multiples of half-integer values, due to the half-integer valued matrix term $\frac{1}{2}((F^T)^{-1}GF^{-1}V^T)$. Meanwhile, $\int_0^L \frac{\partial_x \bar{\theta}_I}{2\pi}$ must have integer values. In the following, we verify that the physics at strong

In the following, we verify that the physics at strong coupling g of cosine potentials still render the decoupled non-chiral Luttinger liquids with integer particle number

quantization regardless a possible half-integer quantization at Eq.(E53). The reason is that, at large g, the cosine potential $g_a \cos(W_{Ja}d_J\bar{\theta}_J)$ effectively acts as $g_a \cos(d_a\bar{\theta}_a)$. In this way, $\bar{\theta}_a$ is locked, so $\partial_x\bar{\theta}_a=0$ and that constrains $\int_0^L \frac{\partial_x\bar{\theta}_I}{2\pi}=0$ with no instanton tunneling. This limits Eq.(E53)'s $\zeta_j=0$ for $j=1,\ldots,N/2$. And Eq.(E53) at large g coupling becomes

$$\begin{cases} \int_0^L \frac{\partial_x \bar{\phi}_I}{2\pi} = \sum_{j=1}^{N/2} (\mathbf{F}^T)_{I,j}^{-1} \zeta_{N/2+j} \in \mathbb{Z}. \\ \int_0^L \frac{\partial_x \bar{\theta}_I}{2\pi} = 0. \end{cases}$$
(E54)

We now conclude that, the allowed Hilbert space at large g coupling is the same as the Hilbert space of N/2-decoupled-copies of non-chiral Luttinger liquids.

Though we choose a different basis for the gapping rules than Ref.47, we still reach the same conclusion as long as the key criteria Eq.(E42) holds. Namely, with $\mathbf{L}^T K^{-1} \mathbf{L} = 0$, we can derive these three equations Eq.(E50),(E52),(E54), thus we have mapped the theory with gapping terms (constrained by $\mathbf{L}^T K^{-1} \mathbf{L} = 0$) to the N/2-decoupled-copies of non-chiral Luttinger liquids with N/2 number of effective decoupled gapping terms $\cos(d_J \bar{\theta}_J)$ with $J=1,\ldots,N/2$. This maps to N/2-copies of non-chiral Luttinger liquids (E-4), and we have shown that each (E-4) has the gapped spectrum. We prove the mapping:

the K matrix multiplet-chirla boson theories with gapping terms $\mathbf{L}^T K^{-1} \mathbf{L} = 0$

N/2-decoupled-copies of non-chiral Luttinger liquids of **(E-4)** with energy gapped spectra.(Q.E.D.)

Since we had shown in Appendix D that for the U(1) theory of totally even-N left/right chiral Weyl fermions, only the **anomaly-free** theory can provide the N/2-gapping terms with $\mathbf{L}^T K^{-1} \mathbf{L} = 0$, this means that we have established the map:

the U(1)^{N/2} anomaly-free theory
$$(\mathbf{q} \cdot K^{-1} \cdot \mathbf{q} = \mathbf{t} \cdot K \cdot \mathbf{t} = 0)$$
 with gapping terms $\mathbf{L}^T K^{-1} \mathbf{L} = 0$

N/2-decoupled-copies of non-chiral Luttinger liquids of **(E-4)** with gapped energy spectra.

This concludes the second approach proving the 1+1D U(1)-anomaly-free theory can be gapped by adding properly designed interacting gapping terms with $\mathbf{L}^T K^{-1} \mathbf{L} = 0$. (Q.E.D.)

5. Approach III: Non-Perturbative statements of Topological Boundary Conditions, Lagrangian subspace, and the exact sequence

In this subsection, from a TQFT viewpoint, we provide another non-perturbative proof of Topological Boundary Gapping Rules (which logically follows Ref.40)

$$\boxed{\mathbf{L}^T K^{-1} \mathbf{L} = 0},\tag{E55}$$

with

$$\mathbf{L} \equiv \left(\ell_1, \ell_2, \dots, \ell_{N/2}\right) \tag{E56}$$

with N/2 column vectors, and each column vector is $\ell_1, \ell_2, \dots, \ell_{N/2}$; the even-N-component left/right chiral Weyl fermion theory with Topological Boundary Gapping Rules must have N/2-linear independent gapping terms of **Boundary Gapping Lattice(Lagrangian subgroup)** Γ^{∂} satisfying: $\ell_{a,I}K_{IJ}^{-1}\ell_{b,J} = 0$ for any $\ell_a, \ell_b \in \Gamma^{\partial}$.

 $\ell_a,\ell_b\in\Gamma^{\hat{O}}$. Here is the general idea: For any field theory, a boundary condition is defined by a Lagrangian submanifold in the space of Cauchy boundary condition data on the boundary. If we want a boundary condition which is topological (namely with a mass gap without gapless modes), then importantly it must treat all directions on the boundary in the equivalent way. So, for a gauge theory, we end up choosing a Lagrangian subspace in the Lie algebra of the gauge group. A subspace is **Lagrangian** if and only if it is both **isotropic and coisotropic**. For a finite-dimensional vector space \mathbf{V} , a Lagrangian subspace is an isotropic one whose dimension is half that of the vector space.

More precisely, for W be a linear subspace of a finite-dimensional vector space V. Define the symplectic complement of W to be the subspace W^{\perp} as

$$\mathbf{W}^{\perp} = \{ v \in \mathbf{V} \mid \omega(v, w) = 0, \quad \forall w \in \mathbf{W} \}$$
 (E57)

Here ω is the symplectic form, in the commonly-seen matrix form is $\omega = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$ with 0 and 1 are the block matrix of the zero and the identity. In our case, ω is related to the fermionic $K = K^f$ and bosonic $K = K^{b0}$ matrices. The symplectic complement \mathbf{W}^{\perp} satisfies:

$$\begin{split} (\mathbf{W}^\perp)^\perp &= \mathbf{W}, \\ \dim \mathbf{W} &+ \dim \mathbf{W}^\perp = \dim \mathbf{V}. \end{split}$$

Isotropic, coisotropic, Lagrangian means the following:

- **W** is isotropic if $\mathbf{W} \subseteq \mathbf{W}_{\perp}$. This is true if and only if ω restricts to 0 on **W**.
- **W** is coisotropic if $\mathbf{W}_{\perp} \subseteq \mathbf{W}$. **W** is coisotropic if and only if ω has a nondegenerate form on the quotient space $\mathbf{W}/\mathbf{W}_{\perp}$. Equivalently **W** is coisotropic if and only if \mathbf{W}_{\perp} is isotropic.
- **W** is Lagrangian if and only if it is both isotropic and coisotropic, namely, if and only if $\mathbf{W} = \mathbf{W}_{\perp}$. In a finite-dimensional \mathbf{V} , a Lagrangian subspace \mathbf{W} is an isotropic one whose dimension is half that of \mathbf{V} .

With this understanding, following Ref. 40, we consider a $U(1)^N$ Chern-Simons theory, whose bulk action is

$$S_{bluk} = \frac{K_{IJ}}{4\pi} \int_{\mathcal{M}} a_I \wedge da_J.$$
 (E58)

and the boundary action for a manifold \mathcal{M} with a boundary $\partial \mathcal{M}$ (with the restricted $a_{\parallel,I}$ on $\partial \mathcal{M}$) is

$$S_{\partial} = \delta S_{bluk} = \frac{K_{IJ}}{4\pi} \int_{\mathcal{M}} (\delta a_{\parallel,I}) \wedge da_{\parallel,J}.$$
 (E59)

The symplectic form ω is given by the K-matrix via the differential of this 1-form δS_{bluk}

$$\omega = \frac{K_{IJ}}{4\pi} \int_{\mathcal{M}} (\delta a_{\parallel,I}) \wedge d(\delta a_{\parallel,J}).$$
 (E60)

The gauge group $U(1)^N$ can be viewed as the torus \mathbb{T}_{Λ} , as the quotient space of N-dimensional vector space \mathbf{V} by a subgroup $\Lambda \cong \mathbb{Z}^N$. Namely

$$\mathrm{U}(1)^N \cong \mathbb{T}_{\Lambda} \cong (\Lambda \otimes \mathbb{R})/(2\pi\Lambda) \equiv \mathbf{t}_{\Lambda}/(2\pi\Lambda)$$
 (E61)

Locally the gauge field a is a 1-form, which has values in the Lie algebra of \mathbb{T}_{Λ} , we will denote this Lie algebra \mathbf{t}_{Λ} as the vector space $\mathbf{t}_{\Lambda} = \Lambda \otimes \mathbb{R}$.

A self-consistent **boundary condition** must define a Lagrangian submanifold with respect to this symplectic form ω and must be local. (For example, the famous chiral boson theory has $a_{\bar{z}}=0$ along the complex coordinate \bar{z} . This defines a consistent boundary condition, but it is not topological.)

In addition, a **topological boundary gapping condition** must be invariant in respect of the orientation-preserving diffeomorphism of \mathcal{M} . A local diffeomorphism-invariant constraint on the Lie algebra \mathbf{t}_{Λ} -valued 1-form $a_{\parallel,I}$ demands it to live in the subspace of \mathbf{t}_{Λ} . This corresponds to the if and only if conditions that:

- \bullet (i) The subspace is isotropic with respect to the symmetric bilinear form K.
- $\bullet(ii)$ The subspace dimension is a half of the dimension of \mathbf{t}_{Λ} .
- $\bullet(iii)$ The signature of K is zero. This means that K has the same number of positive and negative eigenvalues.

We notice that $\bullet(ii)$ is true for our boundary gapping lattice, $\mathbf{L} \equiv \left(\ell_1,\ell_2,\ldots,\ell_{N/2}\right)$, where there are N/2-linear independent gapping terms. And $\bullet(iii)$ is true for our bosonic K_{b0} and fermionic K_f matrices. Importantly, for **topological gapped boundary conditions**, $a_{\parallel,I}$ lies in a Lagrangian subspace of \mathbf{t}_{Λ} implies that the **boundary gauge group** is a **Lagrangian subgroup**. (Here we consider the boundary gauge group is connected and continuous; one can read Section 6 of Ref.40 for the case of more general disconnected or discrete boundary gauge group.)

The bulk gauge group is \mathbb{T}_{Λ} , and we denote the boundary gauge group as \mathbb{T}_{Λ_0} , which \mathbb{T}_{Λ_0} is a Lagrangian subgroup of \mathbb{T}_{Λ} for topological gapped boundary conditions.

Here the torus \mathbb{T}_{Λ} can be decomposed into a product of \mathbb{T}_{Λ_0} and other torus. $\Lambda \cong \mathbb{Z}^N$ contains the subgroup Λ_0 , and Λ contains a direct sum of Λ_0 . These form an exact sequence:

$$0 \to \Lambda_0 \xrightarrow{\mathbf{h}} \Lambda \to \Lambda/\Lambda_0 \to 0 \tag{E62}$$

Here 0 means the trivial Abelian group with only the identity, or the zero-dimensional vector space. The exact sequence means that a sequence of maps f_i from domain A_i to A_{i+1} :

$$f_i: A_i \to A_{i+1}$$

satisfies a relation between the image and the kernel:

$$Im(f_i) = Ker(f_{i+1}).$$

Here we have **h** as an injective map from Λ_0 to Λ :

$$\Lambda_0 \stackrel{\mathbf{h}}{\to} \Lambda$$
.

Since Λ is a rank-N integer matrix generating a N-dimensional vector space, and Λ_0 is a rank-N/2 integer matrix generating a N/2-dimensional vector space; we have \mathbf{h} as an integral matrix of $N \times (N/2)$ -components.

The transpose matrix \mathbf{h}^T is an integral matrix of $(N/2) \times N$ -components. \mathbf{h}^T is a surjective map:

$$\Lambda^* \stackrel{\mathbf{h}^T}{\to} \Lambda_0^*$$
.

Some mathematical relations are $\Lambda_0 = H_1(\mathbb{T}_{\Lambda_0}, \mathbb{Z})$, $\operatorname{Hom}(\mathbb{T}_{\Lambda_0}, \operatorname{U}(1)) = \Lambda_0^*$, $\operatorname{Hom}(\mathbb{T}_{\Lambda}, \operatorname{U}(1)) = \Lambda^*$. Here $H_1(\mathbb{T}_{\Lambda_0}, \mathbb{Z})$ is the first homology group of \mathbb{T}_{Λ_0} with a \mathbb{Z} coefficient. $\operatorname{Hom}(X,Y)$ is the set of all module homomorphisms from the module X to the module Y.

Furthermore, for \mathbf{t}_{Λ}^* being the dual of the Lie algebra \mathbf{t}_{Λ} , one can properly define the Topological Boundary Conditions by restricting the values of boundary gauge fields (taking values in Lie algebra \mathbf{t}_{Λ}^* or \mathbf{t}_{Λ}), and one can obtain the corresponding exact sequence by choosing the following splitting of the vector space \mathbf{t}_{Λ}^* :⁴⁰

$$0 \to \mathbf{t}^*_{(\Lambda/\Lambda_0)} \to \mathbf{t}^*_{\Lambda} \to \mathbf{t}^*_{\Lambda_0} \to 0.$$
 (E63)

Now we can examine the if and only if conditions $\bullet(i), \bullet(ii), \bullet(iii)$ listed earlier in this Section E 5:

For $\bullet(ii)$, "the subspace dimension is a half of the dimension of \mathbf{t}_{Λ} " is true, because Λ_0 is a rank-N/2 integer matrix

For $\bullet(iii)$, "the signature of K is zero" is true, because our K_{b0} and fermionic K_f matrices implies that we have same number of left moving modes (N/2) and right moving modes (N/2), with $N \in 2\mathbb{Z}^+$ an even number.

ing modes (N/2), with $N \in 2\mathbb{Z}^+$ an even number. For $\bullet(i)$ "The subspace is isotropic with respect to the symmetric bilinear form K" to be true, we have an extra condition on \mathbf{h} matrix for the K matrix:

$$\mathbf{h}^T K \mathbf{h} = 0 \tag{E64}$$

Since K is invertible $(\det(K) \neq 0)$, by defining $\mathbf{L} \equiv K\mathbf{h}$, we have an equivalent condition:

$$\left| \mathbf{L}^T K^{-1} \mathbf{L} = 0 \right|, \tag{E65}$$

These above conditions $\bullet(i), \bullet(ii), \bullet(iii)$ are equivalent to the **boundary full gapping rules**: Either written in the column vector of **h** matrix $(\mathbf{h} \equiv (\eta_1, \eta_2, \dots, \eta_{N/2}))$:

$$\eta_{a,I'}K_{I',I'}\eta_{b,I'} = 0.$$
 (E66)

or written in the column vector of **L** matrix (**L** \equiv $(\ell_1, \ell_2, \dots, \ell_{N/2})$):

$$\ell_{a,I} K_{I,I}^{-1} \ell_{b,J} = 0 \tag{E67}$$

for any $\ell_a, \ell_b \in \Gamma^{\partial}$ of boundary gapping lattice(Lagrangian subgroup).

To summarize, in this subsection, we provide a third approach from a non-Perturbative TQFT viewpoint to prove that, for $\mathrm{U}(1)^N$ -Chern-Simons theory, **Topological Boundary Conditions** hold *if and only if* the boundary interaction terms satisfy **Topological Boundary Fully Gapping Rules.**(Q.E.D.)

Appendix F: More about Our Lattice Hamiltonian Chiral Matter Models

1. More details on our Lattice Model producing nearly-flat Chern-bands

We fill more details on our lattice model presented in Sec.III A 2 for the free-kinetic part. The lattice model shown in Fig.3 has two sublattice a(black dots), b(white dots). In momentum space, we have a generic pseudospin form of Hamiltonian $H(\mathbf{k})$,

$$H(\mathbf{k}) = B_0(\mathbf{k}) + \vec{B}(\mathbf{k}) \cdot \vec{\sigma}. \tag{F1}$$

 $\vec{\sigma}$ are Pauli matrices $(\sigma_x, \sigma_y, \sigma_z)$. In this model $B_0(\mathbf{k}) = 0$ and \vec{B} have three components:

$$B_{x}(\mathbf{k}) = 2t_{1}\cos(\pi/4)(\cos(k_{x}a_{x}) + \cos(k_{y}a_{y}))$$

$$B_{y}(\mathbf{k}) = 2t_{1}\sin(\pi/4)(\cos(k_{x}a_{x}) - \cos(k_{y}a_{y})) \text{ (F2)}$$

$$B_{z}(\mathbf{k}) = -4t_{2}\sin(k_{x}a_{x})\sin(k_{y}a_{y}).$$

In Fig.5(a), the energy spectrum $E(k_x)$ is solved from putting the system on a 10-sites width $(9a_y\text{-width})$ cylinder. Indeed the energy spectrum $E(k_x)$ in Fig.5(b) is as good when putting on a smaller size system such as the ladder (Fig.3(c)). The cylinder is periodic along \hat{x} direction so k_x momentum is a quantum number, while $E(k_x)$ has real-space y-dependence along the finite-width \hat{y} direction. Each band of $E(k_x)$ in Fig.5 is solved by exactly diagonalizing $H(k_x,y)$ with y-dependence. By filling the lower energy bands and setting the chemical potential at zero, we have Dirac fermion dispersion at $k_x = \pm \pi$ for the edge state spectrum, shown as the blue curves in Fig.5(a)(b).

In Fig.5(c), we plot the density $\langle f^{\dagger}f \rangle$ of the edge eigenstate on the ladder (which eigenstate is the solid blue curve in Fig.5(b)), for each of two edges A and B, and for each of two sublattice a and b. One can fine tune t_2/t_1 such that the edge A and the edge B have the least mixing. The least mixing implies that the left edge and right edge states nearly decouple. The least mixing is very important for the interacting $G_1, G_2 \neq 0$ case, so we can impose interaction terms on the right edge B only as in Eq.(7), decoupling from the edge A. We can explicitly make the left edge A density $\langle f_{\rm A}^{\dagger}f_{\rm A}\rangle$ dominantly locates in $k_x < 0$, the right edge B density $\langle f_{\rm B}^{\dagger}f_{\rm B}\rangle$ dominantly

locates in $k_x>0$. The least mixing means the eigenstate is close to the form $|\psi(k_x)\rangle=|\psi_{k_x<0}\rangle_A\otimes|\psi_{k_x>0}\rangle_B$. The fine-tuning is done with $t_2/t_1=1/2$ in our case. Interpret this result together with Fig.5(b), we see the solid blue curve at $k_x<0$ has negative velocity along \hat{x} direction, and at $k_x>0$ has positive velocity along \hat{x} direction. Overall it implies the chirality of the edge state on the left edge A moving along $-\hat{x}$ direction, and on the right edge B moving along $+\hat{x}$ direction - the clockwise chirality as in Fig.3(b), consistent with the earlier result $C_{1,-}=-1$ of Chern number.

An additional bonus for this ladder model is that the density $\langle f^{\dagger}f \rangle$ distributes equally on two sublattice a and b on either edges, shown in Fig.5(c). Thus, it will be beneficial for the interacting model in Eq.(7) when turning on interaction terms $G_1, G_2 \neq 0$, we can universally add the same interaction terms for both sublattice a and b.

For the free kinetic theory, all of the above can be achieved by a simple ladder lattice, which is effectively as good as 1+1D because of finite size width. To have mirror sector becomes gapped and decoupled without interfering with the gapless sector, we propose to design the lattice with length scales of Eq.(17).

2. Explicit lattice chiral matter models

For model constructions, we will follow the four steps introduced earlier in Sec.V.

a. 1_L - (-1_R) chiral fermion model

The most simplest model of fermionic model suitable for our purpose is, **Step 1**, $K_{2\times 2}^f = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ in Eq.(21),(22). We can choose, **Step 2**, $\mathbf{t} = (1,-1)$, so this model satisfies Eq.(43) as anomaly-free. It also satisfies the total U(1) charge chirality $\sum q_L - \sum q_R = 2 \neq 0$ as **Step 3**. As **Step 4**, we can fully gap out one-side of edge states by a gapping term Eq.(29) with $\ell_a = (1,1)$, which preserves U(1) symmetry by Eq.(31). Written in terms of \mathbf{t} and \mathbf{L} matrices:

$$\mathbf{t} = \begin{pmatrix} 1 \\ -1 \end{pmatrix} \Longleftrightarrow \mathbf{L} = \begin{pmatrix} 1 \\ 1 \end{pmatrix}. \tag{F3}$$

Through its U(1) charge assignment $\mathbf{t}=(1,-1)$, we name this model as 1_L - (-1_R) chiral fermion model. It is worthwhile to go through this 1_L - (-1_R) chiral fermion model in more details, where its bosonized low energy action is

$$S_{\Phi} = \frac{1}{4\pi} \int dt dx \left(K_{IJ}^{A} \partial_{t} \Phi_{I}^{A} \partial_{x} \Phi_{J}^{A} - V_{IJ} \partial_{x} \Phi_{I}^{A} \partial_{x} \Phi_{J}^{A} \right)$$

$$+ \frac{1}{4\pi} \int dt dx \left(K_{IJ}^{B} \partial_{t} \Phi_{I}^{B} \partial_{x} \Phi_{J}^{B} - V_{IJ} \partial_{x} \Phi_{I}^{B} \partial_{x} \Phi_{J}^{B} \right)$$

$$+ \int dt dx \ g_{1} \cos(\Phi_{1}^{B} + \Phi_{-1}^{B}). \tag{F4}$$

Its fermionized action (following the notation as Eq.(3), with a *relevant* interaction term of q_1 coupling) is

$$S_{\Psi} = \int dt \, dx \, \left(i \bar{\Psi}_{A} \Gamma^{\mu} \partial_{\mu} \Psi_{A} + i \bar{\Psi}_{B} \Gamma^{\mu} \partial_{\mu} \Psi_{B} \right.$$
$$\left. + \tilde{g}_{1} \left(\tilde{\psi}_{R,1} \tilde{\psi}_{L,-1} + \text{h.c.} \right).$$
 (F5)

We propose that a lattice Hamiltonian below (analogue to Fig.2's) realizes this 1_L - (-1_R) chiral fermions theory non-perturbatively,

$$H = \sum_{q=1,-1} \left(\sum_{\langle i,j \rangle} \left(t_{ij,q} \, \hat{f}_q^{\dagger}(i) \hat{f}_q(j) + h.c. \right) \right)$$

$$+ \sum_{\langle \langle i,j \rangle \rangle} \left(t'_{ij,q} \, \hat{f}_q^{\dagger}(i) \hat{f}_q(j) + h.c. \right)$$

$$+ G_1 \sum_{i \in \mathcal{D}} \left(\left(\hat{f}_1(j)_{pt.s.} \right) \left(\hat{f}_{-1}(j)_{pt.s.} \right) + h.c. \right).$$
(F6)

This Hamiltonian is in a perfect quadratic form, which is a welcomed old friend to us. We can solve it exactly by writing down Bogoliubov-de Gennes(BdG) Hamiltonian in the Nambu space form, on a cylinder (in Fig.2),

$$H = \frac{1}{2} \sum_{k_x, p_x} (f^{\dagger}, f) \begin{pmatrix} H_{\text{kinetic}} & \mathcal{G}^{\dagger}(k_x, p_x) \\ \mathcal{G}(k_x, p_x) & -H_{\text{kinetic}} \end{pmatrix} \begin{pmatrix} f \\ f^{\dagger} \end{pmatrix}. \quad (F7)$$

Here $f^{\dagger}=(f_{1,k_x}^{\dagger},f_{-1,p_x}^{\dagger}),~f=(f_{1,k_x},f_{-1,p_x}),~H_{\rm kinetic}$ is the hopping term and $\mathcal G$ is from the G_1 interaction term. Here momentum k_x,p_x (for charge 1 and -1 fermions) along the compact direction x are good quantum numbers. Along the non-compact y direction, we use the real space basis instead. We diagonalize this BdG Hamiltonian exactly and find out the edge modes on the right edge B become fully gapped at large G_1 . For example, at $|G_1| \simeq 10^4$, the edge state density on the edge B is $\langle f_B^{\dagger} f_B \rangle \leq 5 \times 10^{-8}.^{81}$ We also check that the low energy spectrum realizes the 1-(-1) chiral fermions on the left edge $A,^{81}$

$$S_{\Psi_{A},free} = \int dt dx \left(i\psi_{L,1}^{\dagger} (\partial_{t} - \partial_{x}) \psi_{L,1} + i\psi_{R,-1}^{\dagger} (\partial_{t} + \partial_{x}) \psi_{R,-1} \right).$$
 (F8)

Thus Eq.(F6) defines/realizes 1_L -(- 1_R) chiral fermions non-perturbatively on the lattice.

The 1_L - (-1_R) chiral fermion model provides a wonderful example that we can confirm, both numerically and analytically, the mirrored fermion idea and our model construction will work.

However, unfortunately the $\mathbf{1}_L$ - $(-\mathbf{1}_R)$ chiral fermion model is *not* strictly a chiral theory. In a sense that one can do a field redefinition,

$$\psi_1 \to \psi_1$$
, and $\psi_{-1} \to \psi_{1'}^{\dagger}$,

sending the charge vector $\mathbf{t} = (1, -1) \to (1, 1)$. So the model becomes a $\mathbf{1}_L$ - $\mathbf{1}_R$ fermion model with one left moving mode and one right moving mode both carry the

same U(1) charge 1. Here we use $\psi_{1'}$ to indicate another fermion field carries the same U(1) charge as ψ_1 . The 1_L - 1_R fermion model is obviously a non-chiral Dirac fermion theory, where the mirrored edge states can be gapped out by forward scattering mass terms $\tilde{g}_1(\tilde{\psi}_{R,1}\tilde{\psi}_{L,1'}^{\dagger} + \text{h.c.})$, or the $g_1 \cos(\Phi_1^{\text{B}} - \Phi_{1'}^{\text{B}})$ term in the bosonized language. Since 1_L -(- 1_R) chiral fermion model is a field-redefinition of 1_L - 1_R fermion model, it becomes apparent that we can gap out the mirrored edge of 1_L -(- 1_R) chiral fermion model.

It turns out that the next simplest U(1)-symmetry chiral fermion model, which violates parityand time reversal symmetry(but strictly being chiral under any field redefinition), is the 3_L - 5_R - 4_L - 0_R chiral fermion model, appeared already in Sec.II.

b. 3_L - 5_R - 4_L - 0_R chiral fermion model and others

We consider a rank-4 $K_{4\times4}^f=\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\oplus\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ in Eq.(21),(22) for **Step 1**. We can choose $\mathbf{t}_a=(3,5,4,0)$ to construct a 3_L -5 $_R$ -4 $_L$ -0 $_R$ chiral fermion model in Sec.II for **Step 2**. One can choose the gapping terms in Eq.(29) with $\ell_a=(3,-5,4,0),\ell_b=(0,4,-5,3)$. Another U(1)_{2nd} symmetry is allowed, which is $\mathbf{t}_b=(0,4,5,3)$. By writing down the chiral boson theory of Eq.(22), (29) on a cylinder with two edges A and B as in Fig.2, it becomes a multiplet chiral boson theory with an action

$$S_{\Phi} = S_{\Phi_{free}^{A}} + S_{\Phi_{free}^{B}} + S_{\Phi_{interact}^{B}} = \frac{1}{4\pi} \int dt dx \left(K_{IJ}^{A} \partial_{t} \Phi_{I}^{A} \partial_{x} \Phi_{J}^{A} - V_{IJ} \partial_{x} \Phi_{I}^{A} \partial_{x} \Phi_{J}^{A} \right) + \left(K_{IJ}^{B} \partial_{t} \Phi_{I}^{B} \partial_{x} \Phi_{J}^{B} - V_{IJ} \partial_{x} \Phi_{I}^{B} \partial_{x} \Phi_{J}^{B} \right) + \int dt dx \left(g_{1} \cos(3\Phi_{3}^{B} - 5\Phi_{5}^{B} + 4\Phi_{4}^{B}) + g_{2} \cos(4\Phi_{5}^{B} - 5\Phi_{4}^{B} + 3\Phi_{0}^{B}) \right).$$
(F9)

After fermionizing Eq.(4) by $\Psi \sim e^{i\Phi}$, we match it to Eq.(3).⁷⁰

$$S_{\Psi} = S_{\Psi_{A},free} + S_{\Psi_{B},free} + S_{\Psi_{B},interact} = \int dt \, dx \, \left(i\bar{\Psi}_{A}\Gamma^{\mu}\partial_{\mu}\Psi_{A} + i\bar{\Psi}_{B}\Gamma^{\mu}\partial_{\mu}\Psi_{B} \right.$$

$$\left. + \tilde{g}_{1} \left((\tilde{\psi}_{R,3}\nabla_{x}\tilde{\psi}_{R,3}\nabla_{x}^{2}\tilde{\psi}_{R,3})(\tilde{\psi}_{L,5}^{\dagger}\nabla_{x}\tilde{\psi}_{L,5}^{\dagger}\nabla_{x}^{2}\tilde{\psi}_{L,5}^{\dagger}\nabla_{x}^{3}\tilde{\psi}_{L,5}^{\dagger}\nabla_{x}^{4}\tilde{\psi}_{L,5}^{\dagger})(\tilde{\psi}_{R,4}\nabla_{x}\tilde{\psi}_{R,4}\nabla_{x}^{2}\tilde{\psi}_{R,4}\nabla_{x}^{3}\tilde{\psi}_{R,4}) + \text{h.c.} \right)$$

$$\left. + \tilde{g}_{2} \left((\tilde{\psi}_{L,5}\nabla_{x}\tilde{\psi}_{L,5}\nabla_{x}^{2}\tilde{\psi}_{L,5}\nabla_{x}^{3}\tilde{\psi}_{L,5})(\tilde{\psi}_{R,4}^{\dagger}\nabla_{x}\tilde{\psi}_{R,4}^{\dagger}\nabla_{x}^{2}\tilde{\psi}_{R,4}^{\dagger}\nabla_{x}^{3}\tilde{\psi}_{R,4}^{\dagger}\nabla_{x}^{4}\tilde{\psi}_{R,4}^{\dagger})(\tilde{\psi}_{L,0}\nabla_{x}\tilde{\psi}_{L,0}\nabla_{x}^{2}\tilde{\psi}_{L,0}) + \text{h.c.} \right) \right),$$

Our 3-5-4-0 fermion model satisfies Eq.(31), Eq.(43) and boundary fully gapping rules, and also violates parity and time-reversal symmetry, so the lattice version of the Hamiltonian

$$H = \sum_{q=3,5,4,0} \left(\sum_{\langle i,j \rangle} \left(t_{ij,q} \, \hat{f}_{q}^{\dagger}(i) \hat{f}_{q}(j) + h.c. \right) + \sum_{\langle \langle i,j \rangle \rangle} \left(t'_{ij,q} \, \hat{f}_{q}^{\dagger}(i) \hat{f}_{q}(j) + h.c. \right) \right)$$

$$+ G_{1} \sum_{j \in \mathcal{B}} \left(\left(\hat{f}_{3}(j)_{pt.s.} \right)^{3} \left(\hat{f}_{5}^{\dagger}(j)_{pt.s.} \right)^{5} \left(\hat{f}_{4}(j)_{pt.s.} \right)^{4} + h.c. \right) + G_{2} \sum_{j \in \mathcal{B}} \left(\left(\hat{f}_{5}(j)_{pt.s.} \right)^{4} \left(\hat{f}_{4}^{\dagger}(j)_{pt.s.} \right)^{5} \left(\hat{f}_{0}(j)_{pt.s.} \right)^{3} + h.c. \right),$$
(F11)

provides a non-perturbative anomaly-free chiral fermion model on the gapless edge A when putting on the lattice. We notice that the choices of gapping terms with $\ell_a=(3,-5,4,0),\ell_b=(0,4,-5,3)$ of the model in Eq.(F9),(F10),(F11) here are distinct from the version of gapping terms $\ell_a=(1,1,-2,2),\ \ell_b=(2,-2,1,1)$ of the model Eq.(3), (4), (7) in the main text. This is rooted in the different choice of basis for the same vector space of column vectors of \mathbf{L},\mathbf{t} matrices, and the dual structure shown in Eq.(62). Both ways (or other linear-independent linear combinations) will produce a 3_L - 5_R - 4_L - 0_R model.

In Sec.E 4, we outline that our anomaly-free chiral model can be mapped to decoupled Luttinger liquids of Eq.(E22). Here let us explicitly find out the outcomes of mapping. Based on the Smith normal form $\mathbf{L} = VDW$ shown in Sec.E 4, we can rewrite the gapping term matrices \mathbf{L} . From Eq.(E51), the original cosine

term $g_a \cos(\ell_{\underline{a},\underline{I}} \cdot \Phi_I)$ in the old basis will be mapped to $g_a \cos(W_{Ja} d_J \overline{\theta}_J)$. Namely, given the model of Eq.(F9),

$$\begin{pmatrix} 3 & 0 \\ -5 & 4 \\ 4 & -5 \\ 0 & 3 \end{pmatrix} = \begin{pmatrix} 3 & -1 & 0 & 1 \\ -5 & 3 & 0 & -2 \\ 4 & -3 & 1 & 2 \\ 0 & 1 & 0 & 0 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 \\ 0 & 3 \\ 0 & 0 \\ 0 & 0 \end{pmatrix} \cdot \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$$
$$\Rightarrow g_a \cos(\bar{\theta}_1) + g_b \cos(\bar{\theta}_1 + 3\bar{\theta}_2). \tag{F12}$$

On the other hand, given the model of Eq.(7), we have

$$\begin{pmatrix} 1 & 2 \\ 1 & -2 \\ -2 & 1 \\ 2 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 0 & -1 \\ 1 & -2 & 0 & 0 \\ -2 & 1 & 1 & 1 \\ 2 & 1 & 0 & -1 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

$$\Rightarrow g_a \cos(\bar{\theta}_1) + g_b \cos(\bar{\theta}_2) \tag{F13}$$

There are two reasons that we choose Eq.(7) for our model in the main text, instead of Eq.(F11). The first reason is that even at the weak g perturbative level, Eq.(7) flows to gapped phases at IR low energy. In Sec.IV C 3, we have done a perturbative analysis to learn that when $\beta^2 < \beta_c^2 \equiv 4$ for the normal ordered scaling dimension $[\cos(\beta\bar{\theta})] = \beta^2/2 < 2$, the system will flow to the gapped phases. We notice that it is indeed the case for our model Eq.(7) with $\ell_a = (1, 1, -2, 2)$, $\ell_b = (2, -2, 1, 1)$, and the decoupled potentials in the new basis $g_a \cos(\bar{\theta}_1) + g_b \cos(\bar{\theta}_2)$ has $\beta^2 = 1 < \beta_c^2$. The second reason is that the interaction terms for the model of Eq.(7) has the order of 6-body interaction among each gapping term, which is easier to simulate than the 12-body interaction among each gapping term for the model of Eq.(F11).

We list down another three similar chiral fermion models of $K_{4\times4}^f$ matrix, with different choices of \mathbf{t} , such as: (i) 1_L - 5_R - 7_L - 5_R chiral fermions: $\mathbf{t}_a = (1, 5, 7, 5)$, $\mathbf{t}_a = (0, 3, 5, 4)$, with gapping terms $\ell_a = (1, -5, 7, -5)$, $\ell_b = (0, 3, -5, 4)$. Written in terms of \mathbf{t} and \mathbf{L} matrices:

$$\mathbf{t} = \begin{pmatrix} 1 & 0 \\ 5 & 3 \\ 7 & 5 \\ 5 & 4 \end{pmatrix} \iff \mathbf{L} = \begin{pmatrix} 1 & 0 \\ -5 & 3 \\ 7 & -5 \\ -5 & 4 \end{pmatrix}. \tag{F14}$$

(ii) 1_L - 4_R - 8_L - 7_R chiral fermions: $\mathbf{t}_a = (1,4,8,7), \mathbf{t}_b = (3,-3,-1,1),$ with gapping terms $\ell_a = (1,-4,8,-7),$ $\ell_b = (3,3,-1,-1).$

$$\mathbf{t} = \begin{pmatrix} 1 & 3 \\ 4 & -3 \\ 8 & -1 \\ 7 & 1 \end{pmatrix} \iff \mathbf{L} = \begin{pmatrix} 1 & 3 \\ -4 & 3 \\ 8 & -1 \\ -7 & -1 \end{pmatrix}. \tag{F15}$$

(iii) 2_L - 6_R - 9_L - 7_R chiral fermions: $\mathbf{t}_a = (2,6,9,7), \mathbf{t}_b = (2,-2,-1,1)$ with gapping terms $\ell_a = (2,-6,9,-7), \ell_b = (2,2,-1,-1).$

$$\mathbf{t} = \begin{pmatrix} 2 & 2 \\ 6 & -2 \\ 9 & -1 \\ 7 & 1 \end{pmatrix} \iff \mathbf{L} = \begin{pmatrix} 2 & 2 \\ -6 & 2 \\ 9 & -1 \\ -7 & -1 \end{pmatrix}. \tag{F16}$$

Indeed, there are infinite many possible models just for

 $K_{4\times4}^f$ matrix-Chern Simons theory construction. One can also construct a higher rank K^f theory with infinite more models of $\mathrm{U}(1)^{N/2}$ -anomaly-free chiral fermions.

c. Chiral boson model

Similar to fermionic systems, we will follow the four steps introduced earlier for bosonic systems. The most simple model of bosonic SPT suitable for our purpose is, Step 1, $K_{2\times 2}^b = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ in Eq.(21),(22). We can choose, Step 2, t = (1,0), so this model satisfies Eq.(44) as anomaly-free, and violates parity and time-reversal symmetry as Step 3. As Step 4, we can fully gap out one-side of edge states by gapping term Eq.(29) with $\ell_a = (0,1)$, which preserves U(1) symmetry by Eq.(31). Written in terms of t and L matrices:

$$\mathbf{t} = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \iff \mathbf{L} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}. \tag{F17}$$
For $K_{4\times4}^{b0} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \oplus \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, we list down two models:

For $K_{4\times4}^{00} = \begin{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix} \end{pmatrix} \oplus \begin{pmatrix} \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} \end{pmatrix}$, we list down two models: (i) $2_L - 2_R - 4_L - (-1)_R$ chiral bosons: $\mathbf{t}_a = (2, 2, 4, -1), \mathbf{t}_b = (0, 2, 0, -1)$ with gapping terms $\ell_a = (2, 2, -1, 4), \ell_b = (2, 0, -1, 0)$.

$$\mathbf{t} = \begin{pmatrix} 2 & 0 \\ 2 & 2 \\ 4 & 0 \\ -1 & -1 \end{pmatrix} \Longleftrightarrow \mathbf{L} = \begin{pmatrix} 2 & 2 \\ 2 & 0 \\ -1 & -1 \\ 4 & 0 \end{pmatrix}. \tag{F18}$$

(ii) 6_L - 6_R - 9_L - $(-4)_R$ chiral bosons: $\mathbf{t}_a = (6,6,9,-4),$ $\mathbf{t}_b = (0,3,0,-2)$ with gapping terms $\ell_a = (6,6,-4,9),$ $\ell_b = (3,0,-2,0).$

$$\mathbf{t} = \begin{pmatrix} 6 & 0 \\ 6 & 3 \\ 9 & 0 \\ -4 & -2 \end{pmatrix} \iff \mathbf{L} = \begin{pmatrix} 6 & 3 \\ 6 & 0 \\ -4 & -2 \\ 9 & 0 \end{pmatrix}. \tag{F19}$$

Infinite many chiral boson models can be constructed in the similar manner.

- ³¹ We clarify that the chiral symmetry can be regarded as a U(1) symmetry. The **chiral symmetry** is simply a single species fermion's action invariant under the fermion number's U(1) transformation. Each of left or right fermions has its own U(1) symmetry as a chiral symmetry. Thus in our paper we will adopt the term U(1) symmetry in general. The U(1) symmetry in our 3_L - 5_R - 4_L - 0_R chiral fermion model is doing a 3-5-4-0 U(1) transformation, such that the U(1) charge is proportional to 3,5,4,0 for four chiral fermions respectively, when doing a global U(1)'s θ rotation.

- ⁵³ In the case of $K_{N\times N}$ matrix Chern-Simons theory with $\mathrm{U}(1)^N$ symmetry, the Wess-Zumino-Witten model reduces to a K matrix chiral bosons theory. We like to clarify that the K matrix chiral bosons are the bosonic phases field Φ in the bosonization method. The K matrix chiral bosons does not conflict with the chiral fermions (or other chiral matters) model we have in 1+1D. The matter field content Ψ of edge theory is $\Psi \sim e^{i\Phi_I K_{IJ} L_J}$, with some integer vector L_J , where Ψ is what we mean by the chiral matter field content in our non-perturbative anomaly-free chiral matter model.

- By doing fermionization or bosonization, one can recover the chiral matter content in the field theory language, roughly $\psi_I = e^{iK_{IJ}\phi_J}$. One can construct the lattice model by adding several layers of the zeroth Landau levels(precisely, several layers of the first Chern bands), as described in Sec.II,III A 2.
- The fermionization on the free part of action is standard. While the cosine term obeys the rule: $e^{in\Phi} \sim \psi(\nabla\psi)(\nabla^2\psi)\dots(\nabla^{n-1}\psi)$, with the operator dimensions on both sides match as $n^2/2$ in the dimension of energy. Here and in Eq.(7), $g_1 \sim \tilde{g}_1 \sim G_1$, $g_2 \sim \tilde{g}_2 \sim G_2$ up to proportional factors. The precise factor is not of our interest since in the non-perturbative lattice regularization we will turn on large couplings.
